> . . .

If you decide to, I'll be interested in seeing how you do it and what results you get. Reg is the only one I've seen so far who can come up with the impedance of a one-terminal device.

For those of us stuck with needing two terminals to determine a resistance, we find that the RF resistance of a ground rod depends on what's above the ground. That is, the RF resistance of the ground rod is a function of the nature of the antenna. For example, here's the resistance of a four foot ground rod in average soil at 14 MHz, beneath vertical antennas of various heights:

Ant ht ft Ground rod R ohms
16.8 46.2
8.4 34.8
4.2 18.3

These were determined by using NEC-4 and comparing the feedpoint resistance of the vertical over perfect ground with the resistance when connected to a ground rod in average ground. I assume the change in apparent ground rod resistance is due to the change in the field in the ground from the antenna as the antenna height varies.

I want to build some mobile antennas for 10 15 and 20 meters but I am having trouble with the physical design of the coil. My biggest problem is finding readily available material. A shopping list of things to get at the Home Depot would be nice. Antenna would be mounted on my pickup tool box and would like to keep them six ft long so they will fit neatly in the back of the pickup when not in use. I tried this about a year ago and got the antennas to work but the PVC loading coil forms came apart after a while. Any help would be greatly appreciated.

I have also done similar, but a little differently. I used two boards
and drilled between them for the wire diameter. This created two
half-holes in the edge of each board. I laid the wires down in the
holes and laid the other board on top. This sorta worked. I still
had to seal between the glass and the top edge of the bottom window
(we had old recessed windows) so I drilled the holes in the floor.

I've had good luck on those bands using relatively short
lengths of 1.5" diameter, 6 TPI, coil stock and just
tie-wrapping the coil to the middle of the fiberglas rod.

Cecil, what formula do you use for the velocity factor of a coil of diameter D, length L, and N number of turns, in metric units if its convenient.

Do you have a formula for the self-resonant frequency?

Yes. The question is what is the calculated value. B, L, and E
normalized their measurements to the unattenuated field strength at one
mile for 1000 watts radiated power. I couldn't find anywhere in their
paper where they explained how they determined the ground attenuation
between the antenna and their observation point.

> BL&E's measurements, and the results of thousands of measurements made

No, the field strength is strongest at low elevation angles only close
to the antenna, as you further explain below.

> radiator, and the groundwave field it will generate.

Of course the standard far field analysis doesn't accurately depict the field close to the antenna -- it's a plot of the field at points very distant from the antenna, as clearly explained in the manual. NEC allows you to include the surface wave if you want, and it accurately shows the total field including the surface wave at a distance of your choice. (Accurate, that is, up to a hundred km or so, beyond which the deviation of the flat ground model from the curved Earth begins affecting results.)

Don't feel bad -- Reg has a lot of trouble understanding this, too.

> within a fraction of a decibel of that perfect radiator over a perfect
> ground plane, no matter what is the conductivity at the antenna site
> (N.B. Reg).

No, the measured fields from quarter wave broadcast antennas are considerably less than 195 mV/m for 1 kW at one mile, unless perhaps there's only salt water between the antenna and measurement point. As you explained above, the surface wave is attenuated with distance. What you seem to be missing is that the attenuation is strongly dependent on ground conductivity (between antenna and measurement point, not just at the antenna site) and frequency, so the actual field strength at one mile for 1 kW radiated will always be considerably less than the perfect ground case. The 195 mV/m and associated values for various antenna heights is the "unattenuated" or "inverse" field, which doesn't include the surface wave attenuation beyond simple inverse distance field strength reduction. It's the field strength you'd get if the ground between antenna and measurement point were perfect, not what you get over real ground. I'm not very conversant with FCC antenna measurement methodology, but somewhere the measured field strength is normalized to the unattenuated field strength by fitting to a ground attenuation

curve, which in turn depends on frequency and ground conductivity. (I've been told that this is the way broadcasters determine ground conductivity -- by seeing how far the measured field strength deviates from the unattenuated value.) I believe that the surface wave attenuation curves used by the FCC are from the 1937 I.R.E. paper by K.A. Norton. That paper is also the basis for NEC's surface wave calculations.

1387. HF Receiving Antenna & Grounds Question

Newsgroup: rec.radio.amateur.antenna
Date: 2006-04-22 11:52:09 UTC
From: Robert11 <rgsros@notme.com>
Message-ID: <Z4qdnVZjEsh_hdfZRVn-rw@comcast.com>
Source record: 60579

Hi,

In the category of "why the heck didn't I do that years ago," thought I'd relate my experience with a new HF receiving only antenna. Have a JRC 545.

Up to now, have had a simple random length wire running around the four sides of my attic.
Worked, and was able to receive many stations, but was always disappointing.

Bought the PAR EF-SWL antenna, and just put it up outside as an Inverted-L, and away from the house by
about 75 feet or so. Coax run-in to the receiver.
Wow, what an incredible difference.
The noise level is way, way down.

Question; The PAR ends in a Balun, from which I have a wire to a ground bar I pounded into the ground next to it.
From there, the coax starts.

I also have a chassis ground from the radio to a nearby cold water pipe.
Have been putting it on and off trying to decide if it helps to have this additional ground, or hurts.
There is of course the ground loop questions, etc. about having two grounds (the earth ground by the Balun, and this one to the cold water pipe)

Hate to admit it, but am having trouble deciding if it helps.
At times, and for different freq's, I sort of think it
either helps, or makes no difference, at other time, perhaps a bit more noisy.

Most of the time, I believe, it makes absolutely no difference whether this chassis receiver ground wire is on or off.

**Anyone have any thoughts or comments regarding having this additional ground ? **

Should it make a difference ?
I tend to think it shouldn't matter, as they usually suggest grounding the coax, Also, right where it enters the house, which would
be pretty much equivalent.

There is, of course, also the grounding pin of the AC power line, which, pretty much ends up at the same
place, namely a cold water pipe via a ground/neutral wire, from the AC Service Box.

Curious about what all you experts think re these configurations.
Not too sharp with this, and would appreciate any thoughts on.

Thanks,
Bob

1388. Re: Must 300 ohm feedline be kept completely clear of contact w anything?

Newsgroup: rec.radio.amateur.antenna

Source record: 60580

A much simpler antenna is possible at your QTH, based on iteration #4.

Feed your 110 feet long antenna in the center with 600 ohms open wire
tuned feeders [or 450 ohm ladder line ... however, 450 ohm line is more
lossy in bad weather]. You can twist the ladder line at 1 turn every two
feet, or the open wire line 1 turn in 4 feet, to accommodate any
imbalances cause by nearby objects.

If your MFJ 949E does not have a balanced output then use a short
section of coax, 2 to 3 feet is PLENTY, to connect between the MFJ949E
and a MFJ 912 Balun, and then to the tuned feeders.

This is a very low loss setup that should work the following bands with
good to very good antenna efficiency: 80/75, 60, 40, 30, 20, 17, 15, 12
and 10 meters. [My setup, very similar, has a maximum of 1.4 dB loss
across this set of bands using 150 feet of feedline ... 1/4 of an S unit.]

NOTE: The G5RV is in reality a single band antenna!! It is designed for
20 meters where it performs admirably! It can be tuned to work other
bands. However the losses in the coax section can become moderately
high. The CF Doublet with tuned feeders has much lower feedline losses.

> use zero loss conductors versus the loss of the actual aluminum used in
> the antenna?

no, i don't own nec, and don't know enough about it's methods or limitations to trust just throwing together a model to play with on any free version i could get. i have done enough modelling professionally with tools like ansoft/maxwell (for quasi static e-fields), EMTP (for power line transients), TFlash (for lightning transients on power lines), Simulink and EASY5 (electro-mechanical control systems), and some other tools, that i know that if you don't know your tool and it's limitations that any result you generate is questionable. besides, i have enough other things to do this summer putting up new antennas and using them... not enough time to second guess every design out there, I made my choice and I'll take my chances... but the 40m4LLDD i put up last year at 105' seemed to work well over the winter, and much better than the 40-2cd it replaced.... (compared over almost a year now against another 40-2cd that hasn't been moved)... so now i'm replaceing the other 40-2cd with a second 40m4LLDD at 175'. if nothing else it will look impressive, and thats worth 3db or more in the operator's belief that they are loud.

Reg Edwards wrote:
> Cecil, what formula do you use for the velocity factor of a coil of
> diameter D, length L, and N number of turns, in metric units if its
> convenient.

Reg, it's equation (32) from Dr. Corum's paper at:

http://www.ttr.com/TELSIKS2001-MASTER-1.pdf

There is a test in the preceeding paragraph to see if
that equation is appropriate for a particular coil.
Equation (32) is derived from empirical data collected
on coils that pass that test.

Just be sure the diameter, pitch, and wavelength are
all in meters and it will be metric.

I'll send you a .gif file of that page of Dr. Corum's
paper. The graph in Fig. 1 is for equation (32).

While you are at it, take a look at equation (47) for
the characteristic impedance of the coil and let us
know what you think.

> Do you have a formula for the self-resonant frequency?

Here's what I have been doing lately:

1. Using as close as EZNEC can come to my 75m bugcatcher
coil stock, create enough turns for the modeled coil to
be self-resonant on 4 MHz. My 75m bugcatcher coil stock
is ~0.5 ft diameter and 48 turns per foot.

2. Delete enough turns to make it look like my real-
world bugcatcher coil. Use that coil for EZNEC modeling
at 4 MHz.

3. Assume the velocity factor didn't change appreciably
when deleting those turns.

4. Calculate the number of linear feet occupied by the
coil by dividing the length of the coil by the velocity
factor.

5. Calculate the percentage of a wavelength occupied by
the coil by dividing the results of (4.) above, by 246
feet, a wavelength at 4 MHz.

Of all the measurements and modeling so far, this is what
I have come up with as the most accurate estimate of the
percentage of a wavelength occupied by the coil.

And no, it is not 90 degrees minus the rest of the antenna.
The requirement for a purely resistive feedpoint impedance
is that the superposition of the forward and reflected voltages
have the same phase angle as the superposition of the forward
and reflected currents - nothing more.

Message-ID: <124ki4rql72uv5c@corp.supernews.com>
Source record: 60584

Dear Crew:
What may have been lost in this discussion - but often provided by Roy - is the difference between a true surface wave and a sky wave (from the same vertical antenna).

An excellent ground screen at the base of a vertical antenna reduces the losses and thus increases the amplitude of both the surface and sky wave.

A few to several hundred wavelengths from the vertical antenna, the amplitude of the received surface wave is highly dependent on the conductivity of the intervening earth. One could hedge this a bit for frequencies above something like 5 MHz.

At distances from the antenna where the surface wave has become weak, the sky wave dominates. As Roy has pointed out several times: the amplitude of the sky wave is mostly determined by ground properties distant from the antenna - much farther away than any reasonable ground screen will extend.

The sky wave effect may be demonstrated in NEC by effecting a 0.25 WL vertical with a good set of radials over mediocre ground and then changing the ground, at some distance from the antenna, to salt water. (Visualize the antenna being in the center of a circular island and change the diameter of the island.)

Broadcasters at MF, with some exceptions, are interested in maximum surface wave and minimum sky wave. Radio amateurs, for the most part, are interested in maximizing the sky wave. A good radial system assists the radio amateur's goal by improving the overall efficiency. It is the ground distant from the vertical antenna that determines the sky wave.

Hi Bob,

That pretty much defines it, then: no difference.

>Should it make a difference ?

When you moved your antenna away from the source of local noise, your
house, that was the single most difference you could have expected.

>There is, of course, also the grounding pin of the AC power line, which,
>pretty much ends up at the same
>place, namely a cold water pipe via a ground/neutral wire, from the AC
>Service Box.

ALL grounds should go to that connection, even the remote one (and not
through the coax). The addition of that one won't make any DXing
difference, but it is code. It will prevent ground loops, whose
problems run from obnoxious to dangerous.

The capacitor device is very common in most portable radios. It has two sections for AM tuning, and two for FM tuning. The 'screws' adjust trimmer capacitors which are in parallel with the four main capacitors.

You do not specify what frequency you intend to tune the loop to. If you want it for a band of frequencies what range to you plan to cover. I suggest that you take some alligator clip leads and temporarily hook up the loop to one end of each lead. Then try connecting the other ends to different terminals on the capacitor and tune the cap through its range and listen for an increase in noise at the receiver. You will have to tune very slowly as the high Q of

the loop will make the selectivity very sharp and you can miss the noise point easily.

You would be much better off to get some ham to give you a small variable from his junk box. It will work better and will be much easier to mount in the case. With a one meter loop, a capacitor with a value of 100 pf or less should beable to tune between about 7 and 30 mhz.

I have a dipole at 130 feet over a ground screen of 50 radials at least 150 feet long. I have a drooping dipole at 310 feet (ends about 225-250 feet high) and a 195-foot tall 1-foot face series fed tower with 100 200-foot long radials. My soil is red clay under thin topsoil, rolling pasture land and woods.

My friend in Australia has a 40 foot vertical with a top loading coil and a large tubing hat above the coil with 40-50 1/4 wave radials, and a dipole at 100 feet. His soil is terrible.

In many years of blind A-B tests, I find my high dipole barely beats the vertical at distances over a few hundered miles broadside to the dipole, and of course never beats the vertical off the ends of the dipole.

The low dipole (130 feet high) virtually never beats the vertical except within a few hundred miles. The very best it does at a distance is tie the vertical, and only on very rare occasions that mostly occur during geomagnetic storms or at sunrise during strong propagation peaks. The vertical always has less fading.

The VK's signal is most commonly better on his vertical, although he frequently is better on his dipole. Certainly some of that is the lack of vertical antenna efficiency caused by low high and exceptionally poor soil in the Fresnel zone.

I've done thousands of blind AB and ABC tests with stations at many distances, and find the same results.

Right, the question of what the RF resistance of a ground rod doesn't
make sense without the antenna.

What happens if you change the ground rod length to 8 feet and feed
each of those antennas against it?

>
> Should it make a difference ?

You should always isolate the (poor) remote ground of an antenna used
for receiving from the station. There is no code that says it should be
connected to the station.
I isolate the grounds of my Beverage feedpoints from the feedlines,
even though they are thousands of feet from power lines.

The code problem is with grounds at your house, not with the ground at
the antenna. NEC requires all cables entering the house and all grounds
at the house to be bonded to a common point. You should not have a rod
outside for the hamshack ground that is not bonded to the utility
entrance ground. The logic behind this is any surges or lightning hits
will not elevate the two grounds to different potential, and create a
current path flowing through the house.

This is NOT a problem with the ground at the antenna, assuming that
ground is some distance from the house and you have a reasonable length
feedline to the house. What you should NOT do is float the station
without a ground, and you should not have the ground for the station
float independently from the service entrance ground.

If you see a noise change from adding a ground at the house it means
you have a feedline problem, radio problem, or balun or ground quality
problem at the antenna.

> With a one meter loop, a capacitor with a value of 100 pf
> or less should beable to tune between about 7 and 30 mhz.

A 80 cm loop gives me reception between about 5 and 12 Mhz, this is with
a cap from a FM/AM radio kit ...
http://users.fulladsl.be/spb13810/oc/IMAG0018.JPG

So, to have higher freq, the loop should be made smaller ... (or higher
cap ?..)

I have made a loop (single turn too) of 2 X 3 meter, so its diameter is
close to 2 meter, and it gives me about 3? to 6Mhz ... African stations
on 5000-5100 come in very well here near Ypres / Belgium .... (at night)
http://users.fulladsl.be/spb13810/oc/IMAG0017.JPG

I used the 2 meter loop with 3 turns on 1600-1800khz, I could get a lot
of pirate stations from holland and ?? Greece or Serbia ...(at night)
Just turn the loop about 90? to switch between holland and Greece ...

In fact, yesterday I read a wiki about "large" loops (compared to freq,
they are large), on FM. I tried the 80cm loop on FM, and ... oops, it
is very directional, very good... I found stations I haven't had before
...

cite: "The (large) loop antenna is similar to a dipole, except that the
ends of the dipole are connected to form a circle, triangle (delta loop
antenna) or square. Typically a loop is a multiple of a half or full
wavelength in circumference. A circular loop gets higher gain (about
10%) than the other forms of large loop antenna, as gain of this antenna
is directly proportional to the area enclosed by the loop, but circles
can be hard to support in a flexible wire, making squares and triangles
much more popular. Large loop antennas are more immune to localized
noise partly due to lack of a need for a groundplane. The large loop has
its strongest signal in the plane of the loop, and nulls in the axis
perpendicular to the plane of the loop."

Mike Coslo wrote:
>> Most of my measurements have been at
>> the self-resonant frequency of a loading coil.
>
> That isn't the design frequency though, is it?

No, so I changed my approach. My present approach is to
take a self-resonant coil and use only part of the coil
on the *same* frequency, e.g. use half the coil as a loading
coil on the *same* frequency. That way, the velocity factor
should be roughly the same in either case.

> I'm not sure I have this straight. I think I understand Tom's info,
> yet this has me completely baffled.

I accept his magnitude measurements as probably accurate
and reasonable. His phase measurements were meaningless
since standing wave current phase doesn't change relative
to the source and therefore cannot be used to measure phase
shift along a wire or through a coil.

The standing wave current phase is the same from end to
end in a 1/2WL thin-wire dipole. It cannot be used to
determine the phase shift through a wire or a dipole. EZNEC
reports the same thing. This is key to understanding the
misconceptions involved and why the phase measurements were
meaningless.

> Would the short answer be that you do not find any correlation?

Nobody has made a valid measurement of the delay through
a coil. There's nothing to correlate. One cannot use a signal
with unchanging phase to measure that delay.

Make the cap smaller. You can if you put a similar cap in series with
the first you will reduce the total capacity and raise the resonant frequency.
Changing loop length is too much trouble, changing a cap is easy.

A funny anecdote comes to mind in this connection. I was trying desperately to load a very short helical dipole on 40M and ended up hooking it to my old Dentron 1KW matchbox to see if that could do anything with it. Damn antenna loaded up perfectly. SWR at on the line to the matchbox 1.1 to 1, good power transfer at 25 watts from the exciter. So I went to listen with it. NOTHING! NADA! Not even a dit, even though the big vertical array just hummed with CW signals on the band. So I leaned over to check connections and darn near fried my hand on the case of the Dentron. THAT'S where all the watts were going. Damn tuner was loading its own case!

The measurement looks good to me. The phase is exactly what EZNEC predicts -- constant along the wire. The ratio in magnitudes we'd expect depends on the positions along the wire, not just the spacing.

Ian,

Yes, there must be such an equation. Indeed, there must be a dozen of
them.

I am aware that there are a multitude of things which are, or can be
optimised in the design of Yagis.

I am not interested in how gain can be maximised but what it has
actually turned out to be in practice over the years.

It is a statistical function of the number of elements or of boom
length - which are much the same as each other.

It is just a historical fact which all experienced designers must have
a good idea of but, it seems, are reluctant to divulge.

You probably have a good idea yourself. What is it?

For 2, 3, 4 .... N elements?

Ball park accuracy is too good for it.

I would like to include it in the notes to a practical, general
purpose, computer program which estimates received signal strength
from Tx power and ionospheric radio path distance. It could be titled
"How to use S-meters for Novices". ;o)

Dear Cec,

After 3/4 of a bottle of Australian Cabernet Sauvignon, I plucked up sufficient courage to present my printer with Corum's paper.

Lo and behold, it worked perfectly. Even the small amount of color was accurately reproduced.

After speed-reading it I came to the conclusion it is unnecessarily over-complicated. What on Earth does "Voltage Magnification by Coherent Spatial Modes" mean?

For years, my approach to loading coils at HF has been to calculate the inductance and capacitance per unit length of coil from DC principles. And then calculate the velocity factor and Zo from transmission line principles. Which gives results in the right ball park according to what few experiments I have made with actual anennas and helices on the 160 and 80 meter bands.

Then there was G3YXM who deliberately put more turns on the coil on the grounds it was easier to remove them than add to them in case pruning was required. Pruning was required and he ended up by removing all the excess turns.

Have you compared VF's (a critical parameter) in my programs with Corum's values for close-wound coils of usual proportions? I must try to find time to do it myself.

Thanks very much for posting me Corum's paper. I am pleased to see the University of Nis has not been seriously affected by the bombing and guided missiles during the US Yugoslavian attacks. Have the bridges across the Danube been replaced yet?

What I was trying to say was that there is not any single equation relating gain to boom length. In the normal sense of the word "equation", there is no equation at all.

>I am aware that there are a multitude of things which are, or can be
>optimised in the design of Yagis.
>
>I am not interested in how gain can be maximised but what it has
>actually turned out to be in practice over the years.

Ah, then you don't really want equations at all - you want historical anecdotes.

Years ago, I used to collect gain data for long yagis... or at least, such verifiable data as were available at the time... and plotted all the dBd figures on the same piece of graph paper against log(boom length).

The result was a scatter diagram showing a general increase of gain with boom length. For well-designed families of long yagis (eg the DL6WU series) it was possible to draw a good straight line; but there were always a few yagis above that line, and many poorer designs below it.

>It is a statistical function of the number of elements or of boom
>length - which are much the same as each other.
>
It isn't "statistical" in any strict sense of that word. It's just a collection of various isolated individual attempts to make a decent yagi, and all the data include significant measurement errors.

>It is just a historical fact which all experienced designers must have
>a good idea of but, it seems, are reluctant to divulge.
>
Largely because it's all much less meaningful than you imagine.

>You probably have a good idea yourself. What is it?
>
This was before the Internet and before computer modelling, so all I have is an old piece of graph paper. I stopped adding to it in about 1985, when computer modelling became capable of far higher accuracy than amateur measurements.

If anyone wants to try a modern correlation, there's lots of data in the VE7BQH collection:
http://www.ifwtech.co.uk/g3sek/diy-yagi/ve7bqh.htm

VE7BQH's data are all for yagis that might be useful for VHF/UHF moonbounce, so boom lengths start at 1.8wl and range up to 8wl. (This turns out to be no use to Reg - see later - but it's an interesting topic in its own right.)

If anyone is interested in doing it, use the L(WL) and GAIN(dBd) columns. With Excel, it should take all of ten minutes to get the data from the web page and into a "scatter X-Y" graph.

All of these modern long yagis are the results of computer optimization, by people who already know what other designs are achieving. This tends to make all the results bunch closely around the trend-line for the best available performance. Unlike my old plot of stone-age yagis, very poor designs don't make it into VE7BQH's table at all.

Back to Reg:
>For 2, 3, 4 .... N elements?
>
>Ball park accuracy is too good for it.
>
For short yagis, why not use the figures in N6BV's HFTA program? (ARRL Antenna Handbook)

Antenna dBi Boom length @ 14MHz (ft)
Dipole 2.15 -
2-Ele. 5.5 8
3-Ele. 7.0 16
4-Ele. 8.5 26
5-Ele. 9.5 40
6-Ele. 11.0 60
8-Ele. 12.0 80

That is a fair set of "representative" figures.

>I would like to include it in the notes to a practical, general
>purpose, computer program which estimates received signal strength
>from Tx power and ionospheric radio path distance. It could be titled
>"How to use S-meters for Novices". ;o)

So - finally - it all comes out. If the context is "ionospheric", you're not interested in long yagis at all. Why didn't you say so in the first place?

Ian, I have plotted the data in VE7BQH's table, along with a
polynomial (1) curve fit and also the function given by K0TAR for
comparison.

The plot is at http://www.vk1od.net/lost/VE7BQHYagiGain.htm .

It would be dangerous to assume the fit function applies much below
the limits plotted.

I'm looking for 4- 10ft fiberglass poles to rebuild my Flag/Pennant
antenna.
I want to keep it as light as possible, but I want it to last 10 years this
time.
I don't know the strength required. Has anyone used 1" fiberglass for the
spreaders? I'll probably use larger. Tell me what you used and where you got
it.
Thanks, Mike

Source record: 60606

Reg,

I don't think there is a 'formula' that is used to predict gain based on boom length. Several experienced experimenters with boom antennas have stated that the number of elements varies the gain very little for a given length, however, given some general design, a number of elements is typically half the gain of the same design with twice as many elements and twice the boom length.

In other words, a 6 element beam of some given element spacing has a (number from the air) gain of 6db. A twelve element version with twice the boom length will be in the ballpark of 12 db gain.

Given that some 1.5 lambda boom antennas are made for wide bandwidth and others are fine tuned for maximum gain, one cannot have an accurate, or ballpark formula for beams that fit all.

One example is a man who was advertising that his j-pole antenna outperformed a 3 element beam. His comparison was to a 3 element beam designed for 180 deg beam width. It had two reflectors and one driven element, but no director. It had a gain of 2.5 db, if I remember correctly. However, the typical 3 element beam a ham would use is 6-8 db gain and has one reflector, one driven element and one director. It's beam width is much narrower than the 180 degrees desired by the man trying to broadcast his bootleg FM BC station.

I hope this helps.

Let me know.

Maybe making it over-complicated also makes it over-accurate? :-)

> What on Earth does "Voltage Magnification by
> Coherent Spatial Modes" mean?

It means that super high SWRs result in super high voltages.
It's the usual VSWR = Vmax/Vmin for coherent signals.

> Have you compared VF's (a critical parameter) in my programs with

I haven't yet figured out the English unit to Metric unit
conversion procedure for turns on a coil. :-)

You want to rethink this? I've always figured 2.5 - 2.6 dB increase
for each doubling of the boom length (or array size) for practical
purposes.

That's pretty close. I don't know the exact numbers and my numbers
are just ballpark. yours may very well be more accurate. I haven't
tried modeling for accuracy, just what I remember reading about
antennas. If you build a 2 lambda antenna and a 4 lambda antenna, they
the 4 will have about the same gain as a pair of 2 lambda antennas
phased, which is about, but not necessarily exactly double the gain of
one antenna.

give or take 1/2 db, what is that to signal strength anyway?

thanks :)

Buck

It's about 1/12th of an S-unit on your S-meter. Just the thickness of the meter needle.

It matters even less when plus or minus 2 or 3 S-units, or 15 dB, of fading occurs on radio paths through the ionosphere. ;o)

Why all the worry about antenna gains within about 0.01 dB ?

Just get some wire high up in the air and enjoy yourself.

Quite a bit on an EME path.

BTW, going from 6 dB to 12 dB isn't a two times increase.

hi

I was just wondering about how 3 antenna 'types' would compare, I can of course pull the spec's off the manuf home pages, but wonder what a real world interpratation would be and hope somone here might have either used them or have some simular experience to share

a multiband log peridic and traditional multiband beam(w/or w/o traps) and a optibeam

ofcourse there are pro's and con's of each but just wondering what type might be 'mostly best' overall if you tried to just the playing field as level as possible

didn't want this to be about cost per say, just overall performance, but having said that, there sure is a big price swing on those types and I wonder , if anyone one of those antenna types have a overall tremendious benifit based soley on improving received signal strength to warrent one getting it vs say another and or a cheeper one

tnx

Mike:

I've used these military surplus mast sections for flag/pennant supports in
the Caribbean. They are 44-inches per section when stacked, and six is
just right for pennant/flags.

There are other sellers, but this will give you an idea of what I'm talking
about.

Wes, that is pretty consistent with the fit to the VE7BQH collation
which gives me 2.64dB for doubling of the boom length (for a long yagi
(2 - 8 wavelengths) with sufficient elements). Alternatively, 1dB
increase for each 30% increase in boom length.

Owen

You have asked a really broad question. A log periodic antenna will outperform a smaller trap multiband two element beam, but probably not a larger one, i.e. one with longer boom and many elements. You will be as well to abide with the manufacturer's specifications until you can pick out the specific antennas to compare.

A multiband yagi with traps can out perform a trapless multiband yagi, by being longer and using more elements.

I don't know if there is a level playing field unless you can be more specific.

Well known amateur radio antenna manufacturers who have been around a while aren't likely to try to fudge the numbers as too many hams are quick to model the antennas and respond with not so kind words faster than the marketing department can spread their lies. I would trust them for the sake of picking the antennas and then ask around about how they compare.

I would be more wary of satisfied/dissatisfied users information than manufacturers specs these days. Anyone can get lucky and because of that love the antenna. For example, I have communicated three times to Japan from Georgia. All three events were mobile. However, during that same time, I had a tri-band beam up 50 feet and have never been able to make a japanese contact with it. Therefore, one might conclude that my mobile antenna outperforms my yagi. Of course it was propagation and timing.

I used a wonderful trap dipole for about three months. It worked fantastically well. Then I put a fan-style dipole up to test it. It outperformed the trap dipole by a great deal. Until I compared it, the trap was great, now it isn't such a great antenna any more.

This is what you are up against. Good luck.

>

I put together the 15m and 10m antenna today. 10 meter is OK,15 and 20 meter
units have a really high SWR, nearly fullscale on the meter which reads 5:1
max. I figure this may be normal as the impedance of the shorten antenna
should be getting pretty low at this point. 10 ohms or less would not sound
to unreasonable to me for a 6ft long 20m antenna.

I went to the Home Depot today and found some chimney sweeper brush handles
. These are about 4 ft long each made of fiberglass and screw together. A
few of these in the back of the truck will allow me to put together nearly
any length antenna I need. Im thinking 40M may be a practical limit Dont
worry I dont drive and ham at the same time.

Worst problem I see with this is making an adapter for my ball mount. Will
probably cannibalize one of the handles for its attaching hardware and weld
a bolt to it to fit the ballmount

If you're talking about a laptop PCMCIA card, it probably has an antenna on board.

If you're talking about a PCI card that plugs into a desktop and has a removable antenna, I'm sure the power amplifier has protection circuitry.

A high SWR doesn't necessary damage a transmitter that reduces the output power as the impedance goes awry.

I don't think that the designers of 802.11b/g gear are going to be counting on a good SWR at the output anyway, as people are going to shove the computer in the corner with a bunch of cables on it in random orientations/locations with respect to the antenna.

<<>>thanks for the responce buck, I can' make perhaps 2 comments
1. for testing pourposes naturally I would only compare antennas of
'simular' size etc etc as much as apples to apples as possible in other
areas i should have mentioned that.
Well aware that a smaller antenna typically wouldn't do as well as a
much larger in the test world ...or even real world

2. as far as trusting the spec's I do, and mention that, but i wasn't
trying to prove or disprove the manuf spec's simply wondering that if
you had all 3 antennas mounted such that they didn't interfere w/each
other and were close enough not to matter for the test and you had a 3
way switch and you averaged the results which antenna if any would
show an overwelming ''win'

tnx again

1437. APRSPoint new version (3.2)

Newsgroup: rec.radio.amateur.antenna

From: "hxc98@yahoo.com" <hxc98@yahoo.com>
Message-ID: <1145873825.162397.240570@y43g2000cwc.googlegroups.com>
Source record: 60479

This version has several improvements on interface and fixed a few problems raised by users, mainly

1. Connect TCP dialog now remembers all servers, ports and filter strings user enters,

2. Added support for auto GPS connection at startup,

3. Improved handling for station tracking and track line customization,

4. Fixed a bug in weather station data processing,

Newer APRS symbol set support is planned, once we have mappoint 2006 and know more about its API interface. Again, visit http://www.aprspoint.com for further details and download of the latest version. Thanks.

Hi Group,

Over the last few years, I have picked up several of the DirectTV disk which are for 10GHz and most all have a diameter of about 15 to 20 inches.

If I operate a 15 inch disk on 2.4GHz, what gain would I expect?
And, how would this compare to a 20 inch disk?

I am looking forward to your comments!

Cecil,

There is nothing in the concept of superposition that will prevent you from munging up something. I have no idea how you are planning to "superpose" two signals through the same coax, and therefore I have no idea what might happen to the phase.

Go back and review what superposition means. I have stated it here before. It is a standard concept presented in many math, science, and technology textbooks. In simplified form, when superposition applies it says that the output from the combination of two inputs is the same as the sum of the outputs from each input taken one at a time. This is precisely what allows all of the various authors to say that one can consider a standing wave to be equivalent to two opposite direction traveling waves. This is purely a mathematical notion; superposition does not impact the physical reality at all.

Superposition does not always apply. Only systems that are linear can be expected to exhibit superposition properties.

If you choose to add a second input that was not there previously then the combined output will be different than the output from the original single input.

I didn't know I shied away from technical discussions. I thought you were quoting me as one of your gurus when it was convenient.

73,
Gene

I'm sure you will get a more precise answer from those with experience
at 2.4 GHz or who can model the antenna effectively.

For a quick approximation I use the ratio of the square wavelengths. So,
2.4 GHz ~ 5 inch wavelength. A 15 inch [3 wavelength] diameter will
exhibit an approximate gain of 9 square wavelengths or something around
9 to 10 dB at 2.4 GHz. This will most likely may be off target by up to
2 or 3 dB.

Anyone have a more precise estimate or calculation?

1447. MFJ Tuner "Current Balun" conversion.

Newsgroup: rec.radio.amateur.antenna
Date: 2006-04-24 19:59:05 UTC
From: "n3ox.dan@gmail.com" <n3ox.dan@gmail.com>
Message-ID: <1145908745.710199.188670@e56g2000cwe.googlegroups.com>
Source record: 60489

The MFJ-962C "1.5kW" Versa Tuner III description claims to contain a 4:1 current balun. I'm using that "balanced" output on my HF almost-doublet (slightly unequal leg lengths) with fairly decent results.

The balun only has a single core. From what I understand, these "4:1 current baluns" aren't.

Furthermore, my antenna presents both higher and lower impedances than 50 ohms depending on band.

For convenience, I'd like to have a single port that I connect my antenna to at all times. I've remoted this tuner and I don't want to make more complicated switching arrangements. Is it worthwhile to rewind the "4:1 current balun" as a 1:1 choke balun?

It seems that it might be more appropriate for my application. I should expect the core to work well for any HF transmission line transformer I'd like to wind, as long as I don't saturate the thing, right?

I don't know of any way to make a 4:1 current balun with a single one-hole core. I think it's possible with a two-hole (binocular) core if done right.

> Furthermore, my antenna presents both higher and lower impedances than
> 50 ohms depending on band.

The "4:1" transformer probably has a 4:1 impedance transformation only when the load Z is near 200 + j0 ohms. Elsewhere, it'll have a different transformation ratio and also will add series and/or shunt impedance.

> rewind the "4:1 current balun" as a 1:1 choke balun?

Maybe somebody else can take a crack at this, but I think it's impossible to say. It depends on both the differential and common mode impedances seen at the feedline input as well as the tuner's matching range and efficiency.

> It seems that it might be more appropriate for my application. I
> should expect the core to work well for any HF transmission line
> transformer I'd like to wind, as long as I don't saturate the thing,
> right?

I've seen a lot of tuner baluns made with powdered iron cores which don't give enough impedance for a decent balun of any kind. And the flux density will be much greater in a 4:1 voltage balun like you have now than in a 1:1 current balun. Type 43 ferrite is a good compromise choice for a 1:1 current balun. If you want to try using the core, put a bunch of turns on it and measure the impedance with an antenna analyzer if you have one. You'll need about 500 - 1000 ohms to make an effective balun for an approximately matched antenna. It might not be possible to get enough impedance for it to work well on all bands with a multiband antenna.

>Thanks Cecil, I have some old fiberglass 11m antennas, the kind that has a
>wire antenna heatshrinked to a fiberglass rod that would be pefect for
>making this. ....

You can use one of those for all those bands, just by changing the
top "stinger" whip. I use the small hose clamps to hold them, if the
stick doesn't have a slide in mounting part on top.
IE: if you had a 6 ft CB stick that used a short stinger, you can add
length to tune the lower bands. On one of mine, the stinger needed to
be about 2 ft longer to tune 20m using the CB stick. So if you had
various
stingers to clip on, you could work all the bands from 20-10.
On those upper HF bands, even the simple CB stick/extended stinger
will work quite well. A cb/10m stick using a longer stinger to tune
20m,
is more efficient than most 20m sticks using more turns of wire, and a
shorter stinger.
I have one antenna that I've used for nearly 15 years that was built
from a
firestick CB antenna. I added a large coil in the middle, and it works
all
bands 80-10. I change coil taps on the low bands, stinger length on the

upper bands.
I also have one I made from a 6 ft 20m stick. It's also converted to
all
band use, and has the performance of a bugcatcher, being it uses a
large
coil on the lower bands. But...it's as light as a fishing rod n reel...
I use a 5 ft stinger, and the normal driving height of the antenna is
11 ft.
That antenna is exactly center loaded in the driving mode. If I add a
3 ft
mast, it's 14 ft tall, with the coil at the 8 ft level. But I use that
when parked.
Bit tall for driving... :/ Anyway, you can build a pretty good antenna
dirt
cheap if you look around. I've never spent more than junk parts and
chump change for a mobile antenna.

I also made a mistake in that I failed to qualify my statement. I meant only transmission line transformers. A conventionally connected transformer will act as a current balun, and any ratio can be made with a single core. However, it's difficult to get the extreme wide band qualities from one that you routinely get from a transmission line transformer. I don't agree with Trask that his design is a transmission line transformer despite the two holes, but it does seem to have very good bandwidth. Also, although he looked at the return loss with various output terminals grounded, I don't see any measurements showing how well it actually balances the output currents. But most conventional transformers do a good job of that, so this one probably does.

==========

I'm surprised a person of your knowledge asked.

Go to Terman's or other bibles, I'm sure you'll find it somewhere, and find the formula to calculate the DC capacitance to its surroundings of a cylinder of length L and diameter D.

Then do the obvious and distribute the capacitance uniformly along its length.

The formula will very likely be found in the same chapter as the inductance of a wire of given length and diameter.

I have the capacitance formula I derived myself somewhere in my ancient tattered notes but I can't remember which of the A to S volumes it is in.

I'm 3/4 ot the way down a bottle of French Red plonk. But Terman et al should be be quite good enough for your purposes.

And its just the principle of the thing which matters. It's simple enough. I don't suppose you will make use of a formula if and when you find one.

The point is that phase is not preserved through the superposition process and as you have noted before, the phase information completely disappears from the superposed standing wave current.

> This is
> precisely what allows all of the various authors to say that one can

It certainly impacts the physical reality of W7EL's phase measurements. If he measured the delay through the coil using the forward current, he would obtain valid results. If he measured the delay through the coil using the reflected current, he would obtain valid results. But the superposition of those two currents results in a signal with unchanging phase that cannot validly be used to determine the delay through a wire or a coil or anything else.

I did a search quite some time ago and failed completely in finding the formula you describe, in Terman or any other "bible". The formula for the capacitance of an isolated sphere is common, but not a cylinder. The formula for a coaxial capacitor is common also, but the capacitance calculated from it approaches zero as the outer cylinder diameter gets infinite.

Maybe you could take a look after the wine wears off, and see if you can locate the formula. By your earlier posting, it sounds like you've used it frequently, so it shouldn't be too hard to find. I'd appreciate it greatly if you would. And yes, I would make use of the formula -- I'm very curious about how well a coil can be simulated as a transmission line. The formula you use would be valid only in isolation, so capacitance to other wires, current carrying conductors, and so forth would have an appreciable effect. I showed not long ago that capacitance from a base loading coil to ground has a very noticeable effect. Do you have a way of taking that into account also?

Just find the capacitance for a wire of length L and diameter D.

A wire of length L and diameter D is a cylinder.

I vaguely remember seeing, in Terman, in graphical or tabular form,
the capacitance to its surroundings of a vertical wire of length L,
the bottom end of which is at a height H above a ground plane.

If you can't find an equation for capacitance then use the equation
for inductance. The velocity factor for an antenna wire is 1.00 or
0.99. From inductance per unit length you can calculate what the
capacitance per unit length must be to give a velocity factor of 1.00
That's the perfectly natural way I sort things out. My education must
be altogether different to yours.

The equation for capacitance in terms of length and diameter must be
of the same form as inductance with a just a reciprocal involved.

I'm even more certain you will find an equation for inductance of an
isolated wire of length L and diameter D somewhere in the bibles.
From which the equation for capacitance can be deduced.

Hmmm...this is getting back really close to what I was trying to get at when I posted the capacitance-of-a-wire-conundrum basenote a few weeks ago that went nowhere. But since you've opened it up again, I'll toss out some conundrum-ish things about it.

Consider a wire that's perpendicular to a ground plane; obviously this is interesting for a doublet configuration also, because of symmetry.

I believe I can, without too much trouble, find the inductance of a cylinder of current--current in the shallow skin depth of the wire, which is different than the inductance at low frequencies--per unit length. I believe it will be relatively unaffected by distance along the wire.

I believe I can, with a little more difficulty, find the (DC, as you say) capacitance to the ground plane of a section of wire that's short, in isolation from the rest of the wire (as if the rest of the wire weren't there). But I believe that capacitance will be a much stronger function of distance from that short section to the ground plane than was the case for inductance.

That leaves me with a velocity, sqrt((capacitance/unit length)*(inductance/unit length)), that is not particularly constant along the length of wire. I know that things really are like you say: the velocity along that wire will be nearly the speed of light.

So that tells me that something is wrong, and three things come immediately to mind: either the inductance is more variable with distance from the ground plane than I think it is, or the capacitance is less variable, or the DC analysis does not hold when we are dealing with things propagating at about the speed of light.

In fact, there is a clue in the fact that for the whole wire, with one end spaced a very small distance from the ground plane and the other end far away, in a DC case the charge would be clustered near the ground plane, with very little charge at the tip...but in a resonant antenna, there is often a LOT of charge out near the end that's far away from the ground plane.

OK, that ought to be enough to get lots of conflicting responses going!

Cheers,
Tom

Thanks for the input guys.

I think that I'm going to break out the '259B and check antenna impedances on various bands first. I'm probably going to go with the 1:1 choke balun even if the common mode impedance on all bands is not significantly higher than the feedpoint impedance. I guess it shouldn't be worse than what I'm matching now.

I think that I don't actually want a 4:1 transformer, as I know there are a couple of bands where the impedance is fairly low, and if I had a functioning 4:1 current balun, I'd be transforming it even lower before the tuner can take a crack at it, and that just seems counterproductive.

I'm living with some degree of imbalance now (which I've tested in that the antenna SWR is different if I reverse the legs on the "balun" output... they aren't equal lengths, they're whatever I can throw out with a slingshot and a weight after a windstorm)

A 1:1 true current balun on some bands and a not-quite-effective-current-balun on others is probably better than what I've got now...

73,
Dan

Source record: 60507

An important correction: I DO NOT get a lower-than-50ohm *impedance* on
any band.

I may be taxing the limits of my '259B but this is what I measure as
far as ballpark magnitude of impedance.

80M 225 ohms
60m 600 ohms
40m 630 ohms
30m 330 ohms
20m 420 ohms
17m 206 ohms
15m 216 ohms
12m 216 ohms
10m 180 ohms

Nowhere is this resistive.

So, maybe the 4:1 current balun is the more appropriate one. How does
the impedance transformation work with reactive loads?

Here are the impedances if anyone needs:
80m 41-j220
60m 500-j320
40m 500+j370 when paralleled with a 1k resistor (300+j1000ish?)
30m 39-j325
20m 300+j255
17m 50-j200
15m 190+j104
12m 70-j205
10m 170+j60

Will a 4:1 current balun transform a random impedance Z1 to Z2 where
|Z2|=|Z1|/4? I know Roy pointed out that this won't work for a voltage
balun...

What is the transmission mode in a single conductor transmission line?
Does a coil support TEM waves, TM, or TE? Is there some type of
cutoff frequency?
How do you compute the phase velocity? How do you know the phase
velocity of an electromagnetic wave on a coil of wire isn't greater
than the speed of light in the helical direction?
People like Reg and Cecil like to simplify things to the point of
absurdity. Things that complicate the picture and disagree with their
simplifications are promptly ignored. I hope no one reading these posts
is under the false impression he's learning transmission line theory.

No, it won't either. The amount of error with any balun type depends on the balun construction. You'll just have to build one and see what it does.

It would be interesting to know what your antenna Z looks like on each band at the input to the existing balun. That is, what do you get when you connect your antenna to the balun output and the analyzer to the balun input?

Since the balun is connected to a tuner, inaccurate impedance
transformation won't matter much. The only concern would be if it's a
sign of some other problem in the balun.

For a monster 4:1 current balun of the type that has two independent
'cores', see page 30 of:
http://www.yccc.org/Articles/W1HIS/CommonModeChokesW1HIS2006Apr06.pdf
(or for short: http://tinyurl.com/qnzs3)

The whole article is about common-mode chokes, and is well worth
reading. It shows what can be done to tame a "noisy" QTH, if you're
prepared to go to extreme lengths... and this guy certainly was!

Well, yes and no. Good tuner designers go to a lot of trouble to maximize the Q of the inductors to minimize loss. It's doubtful that the Q of the balun inductance is nearly as good, so loss is liable to be higher if the balun is contributing a significant amount of reactance. Otherwise, I agree, it doesn't make much difference. The balun might move the impedance to a point where the tuner can't match it, but it's just as likely that it'll move an otherwise unmatchable impedance to within the tuner's range.

A choke balun has NO impedance or turns ratio. It is silly to refer to one.

To make one just wind 15 or more turns of twin speaker wire on a 2" diameter, one-hole, ferrite core.

A one-hole core is a ring with a hole in the middle.

Ferrite permeability need not be high. 200 or 300 is good enough and will provide enough inductance to cover the 160m band. Low permeability materials also have lower loss at the higher frequencies. Not that a choke balun is a lossy component. Efficiency is extremely high.

Because the length of wire is only about 1/8th of a wavelength at 30 MHz it will be ok at that frequency too.

All the talk about saturation is so much hot air. You couldn't saturate it even if you tried. The currents in the two wires run in opposite directions and cancel each other out.

It has a a lower loss and higher power-handling ability than a core wound with the usual very small diameter coax.

Consider me silly as well as an "old wife". A choke balun has common mode impedance, and that impedance is its single most important quality. If the common mode impedance isn't adequate, it won't perform its function. It can be measured by short circuiting the input conductors together and output conductors together to temporarily make one conductor, and measuring the impedance between the ends.

> . . .

> All the talk about saturation is so much hot air. You couldn't
> saturate it even if you tried. The currents in the two wires run in

I agree that saturation isn't a problem, but disagree about the reason. Core flux density is a function of the common mode current, which is in the same direction in the wires and doesn't cancel out. The objective of the balun is to minimize this current, but in a high power system even with an effective balun, the I^2 * R loss, where I is the common mode current, can still get large enough to make the core hot. However, if you use a high-permeability, low frequency ferrite, the flux density will still be way below saturation even when the core is hot enough to break.

Dan,

That is correct. It is impossible to make a single core (single hole) transmission line balun of any ratio other than 1:1. The MFJ balun, if you actually test it, adds terrible imbalance to the system. I know because I actually bought and measured one.

The idea for that balun came from Jerry Sevik's book about baluns and un-uns....but unfortunately the suggestion is wrong.

Trask claims to have a transmission line balun on a single core, but he actually has a simple isolation transformer. Isolation transformer designs are old as dirt. You'll see in my articles on my web page and things I wrote for ON4UN's low band DXing book that I used isolation transformers for many years on low frequency receiving antennas, as have many other people. The problem using them for transmitting is loss, possible core saturation, and core heating. The flux density in the core is very high under any load condition. They also go out of balance badly at higher frequencies.

Bottom line is the single core 4:1 current balun used by MFJ is very poor for balance, and subjects the core to unnecessary flux density. I'd get rid of it for those reasons.

Tom is correct in every respect, though he doesn't need me to confirm this. It is fairly easy to show that the Trask transformer is electrically equivalent to the popular trifilar-wound 4:1 voltage balun when wound on a single toroidal core. As such, it has no output (I wound and measured one) into a fully unbalanced load, and of course it has no choking action at all.

I do not know about binocular cores. It would seem the transformer works somewhat into an unbalanced load when built with these, maybe due to imperfect flux coupling between the two holes? I haven't measured one. And neither has Trask himself. Until he produces a true transfer function plot into a balanced and fully unbalanced load and a choking impedance plot we are left to guess. To use return loss plots to infer correct operation of a two-port network is, um, unusual.

To the extent that the balun is working, it will work with complex
impedances as well as with a purely resistive ones.

The Trask paper has several designs for 2 core 4:1 current baluns that
should work. They need two cores. If you want really wide band
performance, you can stack a low frequency and higher frequency
ferrite toroid for each of those cores. With this approach you can
achieve a 1000 to 1 frequency range. The long tube bead ferrites make

good baluns in a small space.

Tom and others,

I'm wondering if anyone wants to comment on Andrew Roos, ZS1AN article
in the Sept/Oct 2005 QEX issue titled "A Better Antenna-Tuner Balun"?
Andrew placed a 1:1 choke balun in tandem with a 4:1 voltage balun and
claims an improvement over the more conventional methods.

The article is available for ARRL members at:
http://www.arrl.org/qex/2005/qx9roos.pdf

Tom, the original question is a single conductor transmission line. A
single conductor transmission line is used to feed a 'classic Windom'.

In that configuration, is it a G line?

For the uninitiated, including this questioner, what is a G line?

I don't believe a single bare wire will operate as a transmission line
in free space. It will radiate. G line, on the other hand, will not.
At least it won't radiate any more than a piece of coax. And it can be
used in reasonably normal situations, but no sharp bends. It is not
practical for HF, however. 70 cm would probably be as low as you would
want to go.

The quick description is that G line is a wire coated with a dielectric
to a specific thickness that is coupled to by a device resembling a
feedhorn on each end, where the horn is a flaring of the shield. As I
remember it, the dielectric discontinuity constrains the E field, and
hence the EM field. The losses are much lower than coax, on the order
of 5 dB per mile at 500 MHz.

For details see -

http://coldwar-c4i.net/G-Line/EE0860/p638.html

I had taken an old CB 6ft antenna, the kind with the wire heatshrinked to the side and put new wire and a loading coil in the middle. Works OK on 10 and 15 SWR is pretty high on 20 and I dont have a way to match it. Experimented with a cane pole for a support and found I could get a reasoable SWR on 20 if the antenna was about 14ft long, a couple more feet and I wouldnt even need the coil. Next plan is to try to use something that folds kind of like fiberglass tent poles and get away from the loading coils all together. They are more of a bother than what they are worth for my application since I dont ham while Im driving. I just wanted something I could store neatly in the back of the truck which would limit eveything to 6Ft or less. Changed my mind about 5 times now on what I want and how to do it, I guess that happens when you are going up the learning curve.

Let's say we have a 1/2WL dipole in free space driven by a
self-contained source at the center. If we float a florescent
light bulb around the ends of the dipole, are you saying the
electric fields won't fire the bulb like it does on earth?

Ian... extreme lengths is right! I like the ferrite cores strung onto
the 240V lines.

I'm sure this approach would help if I wasn't on a graduate student
budget and living in an apartment (though maybe I could sneak around
and install snap-on ferrites on everything?)

After reading that article and thinking back a bit, I think a real
current balun would be worthwhile.

A previous incarnation of my "invisible" antenna used *one* length of
magnet wire to a SO-239 tuner center pin and used the balcony rail
connected to the ground on the tuner.

Switching to the "balun" and two legs reduced my electric(al/onic)
noise quite a bit. I think at least trying to enforce balance is
worthwhile. I guess I need to be prepared to spend some money if I
want to be able to choke off common mode currents on all bands .
I certainly am trying to tame a noisy QTH, but I've made some progress.
As is often the case, it was mostly *my* stuff causing the noise.
Still, I've got a few persistent sources. I know *some* of it is
radiated and I'm sunk there. My 6m antenna is a moxon rectangle with a
string of 60 or so #43 beads as a balun mounted on a fiberglass mast.
Everything it's picking up is radiated :-)

Roy, I'll do the impedance measurement on the balun input, just as a
matter of curiosity, and post the results.

First pass, I think, will be the 1:1 current balun, especially if the
MFJ balun's core is of a worthwhile material. I'll let the tuner do
its job.

I'm curious about what would happen with the 4:1 current balun, butI'll
have to order some cores.

Some more info here: http://www.answers.com/topic/goubou-line

If you search for Goubou line AND Goubau line, you can find lots more. Older editions of "Reference Data for Radio Engineers" had design info on them.

The losses, as with any good line, are mainly due to I^2*R loss in the wire. The current is lower than it would be for the same wire in coax, for a given power, and thus the loss is lower. "YMMV" when it rains, or when the line gets coated with soot and grime.

I believe I've seen it described as "quasi-TEM". Clearly if you look immediately next to the wire, you'll find magnetic field symmetrically encircling the wire, and electric field is always perpendicular to good conductors so the electric field is radial. That's the same as in coax, but if you look at the article Tom posted a reference to, you'll see that the field lines do not remain perpendicular to the wire further out.

Cheers,
Tom

>further out.

According to Goubau's original paper [1] the mode is a surface wave which is attached to the wire, but decays over a distance of a few wavelengths sideways from the wire. Unlike a normal TEM wave, the energy in this surface wave remains confined to its cylindrical near field, and does not radiate into the far field. Its only direction of long-distance propagation is along the wire, which is what makes it usable for transmission-line purposes.

The surface wave also has the rather odd property that on a bare wire of infinite conductivity, it will not propagate at all! However, it will propagate successfully if the wire is coated with a magnetic or a dielectric material, and for practical applications Goubau favoured various forms of insulated wire.

The practical problem is that the surface wave requires a feedhorn of several wavelengths in diameter, to selectively excite this particular mode without also exciting the radiating TEM mode. Out along the wire, any disturbance to the propagating fields tends to cause mode conversion back into TEM, which makes the G-line revert to radiating like any normal wire antenna. When the wire is viewed as a transmission line, any far-field radiation represents a loss.

To sum up, the G-line surface wave is very different from the normal TEM waves around an isolated wire. Unless you take specific steps to excite this particular mode, it won't occur at all, so it isn't relevant to the

main topic under discussion.

It's a mistake to think that just because an antenna looks like it has one wire (although it really always has two) that it bears any similarity to a G line in operation. Whatever mode a G line effects, it isn't the same as an antenna -- a G line doesn't radiate significantly unless bent or improperly constructed.

I appreciate Danny's question as it allowed me to pull out that article, which I had marked for more careful study. I'm not a transformer expert but two things about the article strike me:

1. Andrew seems to have the transformers connected in the wrong order. If he wants the 1:1 current balun to operate at a lower impedance it should be on the 50 ohm side of the voltage transformer, I should think.

2. Andrew fails to compare his scheme with its most obvious competitor, the 4:1 two-core Guanella current balun. This would be an interesting comparison as the Guanella can use smaller cores (did you see the size of the voltage balun in the picture? Pretty big compared to the current balun), but the windings operate with 100 Ohms impedance at each end instead of 50.

But Andrew's scheme ought to basically work, and better than any single core scheme. I'll bet the experts on this list could help further.

Ian,

Thanks for the explanation. It was very helpful as well as concise.

And I didn't think it had much to do with the main topic when I diverted
to this one, except for the phrase "single wire transmission line", but
that never stopped anyone else here before! ;)

The imaginary part of these numbers seem a bit odd (oh no, only three
of them are odd--the rest are even). Is your antenna resonant on any
band?
I'm probably not well-versed in all the impedances an antenna/feedline
can take at the tuner, but would like to know what antenna and feedline
this is.

>1. what will happen when you have two transmitters(digital spectrum) @
>the same carrier freqeuncy and is received by a superhet receiver
>exactly at the same time, although unlikely (2.4ghz ISM band)

The same thing that happens in any similar situation at lower
frequencies. The two carriers will interfere. Unless they are
accurately locked to a common frequency reference (unlikely) there
will be a significant beating between them. The information-carrying
sidebands of the two transmissions are likely to interfere, and the
transmissions are likely to be garbled at their intended reception
points. The degree of garbling/interference will depend on the signal
strengths and also on the modulation scheme used.

>2. what are ways and means to prevent this collision?csma/ca?rts/cts
>setup?how?

There are several approaches which have been used.

The simplest is probably CSMA/CA, where each stations listens, doesn't
transmit when it detects a carrier, and waits for some variable amount
of time (often randomly-chosen) after carrier goes away before it
starts transmitting. You'll tend to find this used in ad-hoc networks
of various sorts, where there's no central coordinating authority for
the right-to-transmit. For example, most amateur-radio AX.25 packet
networks here in the US work this way. Collision rate tends to go up,
and bandwidth utilization maxes out and decreases when there are many
stations trying to operate on a single frequency.

The classic problem with CSMA/CA on radio is the "hidden node"
problem. If two nodes can't hear one another, they can't avoid one
another... and their transmissions can often both be heard at other
stations and will interfere.

A second approach is an RTS/CTS system, coordinated by a central node
which can be heard by all other nodes. This is a common mode on
802.11b networks, where coordination is performed by the 802.11b
access point.

A third approach is a polling approach, where the outlying nodes never
transmit (not even an RTS) until specifically polled by the central
authority-node. I believe that many of the AX.25 packet networks in
Europe use this approach, in order to minimize collisions and improve
bandwidth utilization over what's possible with CSMA/CA.

If there's no central authority to handle polling or RTS/CTS, then some form of ad-hoc "token passing" can be used, where each node receives an explicit handoff of the right-to-transmit from another node, and either sends what it has to send, or forwards the right-to-transmit packet to the next node in the sequence.

Time-division multiplexing (e.g. slotted Aloha) is another method... nodes coordinate to agree on which time slots each is allowed to transmit in. This can minimize or eliminate collisions (except perhaps during setup) but it can waste bandwidth, because timeslots can go unused if the nodes which "own" them don't have anything to say at the moment.

So - there are lots of approaches - which one is best depends a great deal on the environment and application.

Regarding the use of English, I will interpret your opening line as excluding Tom and me from the ranks of nitpickers. Thank you for the comma.

Indeed, we build our world on approximations. Even Maxwell and friends gave us only approximations, though ones that are far better than we need for the things we do with our HF or even microwave antennas.

But if I'm given two DIFFERENT ways to approximate the same thing, and they give me VERY different answers, then I'd like to understand the situation better. In other words, I'm exactly interested in that art you mention, and in being able to judge when others claim to know that art but in fact do not. They can try to lead me astray, but I don't have to let them.

In other words, if you or anyone else gives me answers, directly or through graphs or computer programs or whatever, I'd like to be able to judge the validity of those answers for what I'm trying to accomplish. I trust that's not a goal you'd disagree with, but perhaps you will.

I also am much more wary of people who just give answers with no indication of the degree to which they are approximations, than I am of people who explain that their answers are approximations and to what degree and why they are.

In this case, I happen to think that it's worthwhile understanding WHY the DC capacitance isn't very useful in the dynamic situation of an antenna. Thankfully, for those who can't figure that out for themselves, there are some decent explanations kicking around.

Cheers,
Tom

Reg, G4FGQ wrote:
"I`m even more certain you will find an equation for inductance of an isolated wire of length L: and diameter D somewhere in the bibles."

Equation 14 on page 48 of Terman`s 1943 edition of "Radio Engineers` Handbook is:

Lo = 0.00508 l (2.303 log 4l/d - 1+mu/4) microhenrys

Lo is the (approximate) low-frequency inductance and the dimensions are in inches.

Terman also gives the (approximate) low-frequency inductance formula of a single-layer solenoid on page 55 of the same book.

One can find the resonant frequency of the coil when using a known capacitance to resonate the coil at a low frequency. Maybe a dip meter could be used. Capacitive and inductive reactances are equal at resonance. Self and stray capacitances are included with the known value of capacitance used to resonate the coil at the low frequency. The resonant frequency is lower than the known capacitance by itself would produce.

The resonance formula used with the actual inductance of the coil will give the capacitance of the resonant circuit

The difference between the calculated capacitance and the known capacitor value is equal to the stray and self-capacitance total, so it is good to minimise stray capacitance when seeking the self-capacitance value of the coil.

An ARRL Single-Layer Coil Winding Calculator is a slide rule which makes things easy.

Best regards, Richard Harrison, KB5WZI

My antenna is not resonant on any amateur band. It gets almost there
around 4.1MHz.
(SWR 1.8:1 or something) It's an unequal leg length variously bent
doublet made with whatever length of 30 gauge magnet wire I managed to
fling out into the trees on that particular occasion.

Approximately: one leg 60 feet long about 24 feet high at the feed,
about 35 feet high at the other end. The other leg about 50 feet long,
bent groundward at a point 35 feet up and 30 feet out with an almost
vertical descending portion.

The "feedline" is a slightly tapered open wire section of the same
magnet wire with more or less 1.25 inch spacing. It's only about 4
feet long.

The antenna tuner is hidden in a big blue wooden box on my balcony
directly under the antenna feed, so I don't need much of a run of
feedline. I set plants on it.

The length numbers are *very* approximate. I've paced out the
tree-balcony distance and also checked with google earth, but I figured
a tape measure might be a bit suspicious.

I actually have very little trouble tuning the antenna. I do have a
lot of noise and removing all I can of the conducted component would
serve me well, I think.

I have been trying to get an acceptable 2 meter antenna installed in my attic. A J-Pole seemed to me the best solution for my attic space. You may recall an earlier post where I discussed SWR on one of the ladder line J-Poles I was working with. Well, I gave up on ladder line and constructed a J-Pole from 1/2 inch copper tubing. I tuned it in my basement work shop to give the best SWR and then took it up to the attic. The following table shows the results.

Basement Attic

144 1.90 1.80
145 1.65 2.00
146 1.50 2.10
147 1.60 2.25
147.995 1.90 2.25

Actually, probably not that bad for a first attempt at copper tubing. But, I didn't like the fact that SWR was above 2.0 in my attic and that things changed between my basement shop and the attic. I guess this design is influenced by objects close by.

So, somewhere in my surfing I came across the Arrow J-Pole. This is an end fed, open stub commercial design that promises less that 1.5 SWR across the band. Here are the results of my experiment with this antenna.

Basement Attic

144 1.10 1.22
145 1.18 1.10
146 1.25 1.20
147 1.30 1.32
147.995 1.40 1.42

Not 1.0 SWR but certainly met the promise. And the best thing about this design is that near by objects don't seem to have an impact on performance. If I built one of these designs and tuned it in my basement shop, it should give the same results in the attic.

Anyway, just my subjective observations.

That's all very nice. Let's see if it's useful for anything.

A while back, Cecil posted a model of a base loaded vertical antenna. It has an inductor which is vertically oriented. The bottom of the inductor is 1 foot from the ground and the inductor is 1 foot long and six inches in diameter. Inductance is 38.5 uH and it's self resonant at 13.48 MHz. (Moving it very far from ground changes the resonant frequency to 13.52 MHz.)

What's it's velocity factor, and how did you calculate it?

Roy, I can't answer the question you put to Reg, but the capacitance of an isolated conducting cylinder is approximately that of an isolated conducting sphere of the same surface area. Any unbalanced charge on a conductor resides on the surface of the conductor and so the greater the surface area, the greater the charge you can place on it to raise its potential by some amount, etc. Obviously the cylinder's electric field would depart from the radial field of a point charge at the center of the sphere but I don't think that's relevant in this case. I hear bells ringing. ;-)

Hi Jimbo, it has been my experience, and everybody else's that an indoor or attic J-pole is unpredictable. A high impedance end fed antenna in an attic environment will be hard to predict. Moving it one foot can effect things.
You might consider the SO-239 ground plane. It can be built and tuned in 30 minutes, is 50 ohms, so it will not be so concerned about its environment. Likely you could not tell a difference in performance from a J-pole especially if they are both in the attic.
Oh yes, the standard-if the SWR is below 3.0, don't worry about it.

I started building dipole antennas. they can be mounted horizontal or
vertical and easily moved around. I use cpvc with a dipole wire
inside and a coax-choke balun. They work quite well.

Just another option.

Buck, when I saw them there wasnt a price on the handles so I went back today to check. All of the chimney sweep items were gone. I checked and found that these items are seasonal and wont be back out until August or September, day late and a dollar short. It doesnt make sense to me, this is the time of year that they should be out. I have never cleaned a chimney but have had it done and you dont do it during the heating season.

Oh well, I still think these have great possibilities as antenna parts barring they dont turn out to be super expensive.

Is there a place on the net, in a book, etc. that I can see examples & diagrams of a coax bulkhead? My house sits on a slab and I want to run about 4 or 5 coax cables, rotor cable, AC & DC source all going from the shack to my tower. In Florida lightning is a major concern so the bulkhead will have to have coax & other type of arrestors. All this is grounded to a copper ground rod & the cables, of course, to my shack. I would like this outside "box" nicely & neatly dressed & labeled so it's easy to disconnect & not an eye sore. I searched the Ham books and many Internet sights to no avail. Anybody? Thank you.

Not to detract from the other posters ... IMO they all made valid comments, but I offer this:

As the builder of about 20 copper pipe j-poles, I discovered that I can get a better final VSWR if I include a 100 pF (or so) cap in the side fed by the coax center.

I had been attaching an SO-239-type bulkhead connector to the short side of the J and running a piece of solid wire from the center pin over to the long side of the J. I could get the VSWR to a dip near the middle of the band by monkeying with the feed point and/or trimming the length but the lowest I usually got was around 1.5 : 1. As soon as I used the cap in place of the straight wire, I could get 1:1. It works for me ... your mileage may vary.

I built more j-poles for 2M than all the others combined and 20 is not a lot of antennas. For some reason, the cap seems to help the 2M size more than it helps the others, but these antennas are too few in number for scientific judgements by this amateur plumber.

73,
John

Message-ID: <1146037614.794897.304330@u72g2000cwu.googlegroups.com>
Source record: 60461

There are quite a few ways you can match them. You can use a
coil at the feedpoint, IE: like the "dollar special" matcher in the
handbooks, or you can use an L tuner, or sometimes just a cap alone.
A few turns of the loading coil can be applied as part of the matching
too
if needed. Most of the "stick" antennas have the matching coil wound
at the base of the antenna. Most any old tuner would match it. Even a
cheap random wire tuner would work fine. You just reverse the
connections
for low Z use if you need to.
With the 6 ft stick I have, I put the coil at the top, and then added 5
ft of
stinger on top of the stick. So it came out center loaded, being the
coil
is a few inches long. The first one I built had the coil about 2.5 ft
above
the base. I still use it on the truck when I'm whacking a lot of low
trees.
I use the tall coil version when I more out in the clear. On my play
truck,
the mount is up on the cab at 64 inches from the ground. I hit trees a
plenty,
but have never hurt one of the antennas yet. The stinger just bounces
off
most of the time, and if I do hit the glass part, it just bends and
snaps
back. I don't use a spring. On the higher HF bands, even a loaded
antenna will still work real well. Even most hamsticks unmodified
will do ok. Both mine use fairly large coils. About 2.5 -3 inches
dia...
So electrically, about the same as a bugcatcher as far as performance
without all that heavy weight that the average bugcatcher entails.
I use the 3 ft mast at the base when parked, and on the low bands.
The coil is nearly 8 ft above the cab and the tip of the antenna at
about
19 ft. Kicks butt, even on 80m.. :)

Source record: 60462

Dunno about yagi's in particular, but for verticals I always had good luck with thin elements. I have a 40 m ground plane I built from a junk 5/8 cb antenna. I just added thinner and thinner tubing to reach 32 ft. The top 3 ft was actually a whip from a mobile antenna. It would bend a good bit in strong wind, but never broke, and always bounced back up straight after the wind was gone. Anway, I think ice might make the thin yagi elements droop a bit, but I kinda doubt they would break.

Once melted, should look normal. C/C elements dropping? Dunno... That would have to be some rusted out hardware. I just got a C/C 4218 this past weekend, and looking at it, I really doubt it's going to

be dropping any elements. The bolts holding the clamps would have to break. That antenna should brown the food on 144 mhz... :) I got it dirt
cheap, and it's all intact. Just needs a cleaning, and I think I'm going
to change the hardware to stainless if I ever stick it in the air.
I use a homebrew 3 el for 6m made completely from copper tubing.
It's all welded together one piece. I also got a free drake R4C this weekend...It was real dirty, but I've semi cleaned it up, turned it on, and danged if it doesn't work half decent... So now I've got one of the

first R4's ever built, and one of the last... My old R4 is #0058... One of the first churned out in 65... This C line radio is #22971...I guess

they built a few... I still got some more work to do on it, but I think it
will clean up pretty nice.

Don't use the 'gap' type arrestors for the antenna feeds. They look
great, but by the time the spark jumps, it will have fried your
finals. Use the gas types where the charge is arrested more quickly
than the gap styles.

There is much correspondence on these walls about protecting equipment and property from lightning strikes. But there is never anything said about protecting people. Where are your concerns?

In this country, UK, I can't remember the last time I read in the newspaper about anybody being killed by lightning. It is extremely rare.

It doesn't appear to give US citizens much cause for concern. Are you all very brave? Or have you just got used to it.

Just curious. What is the annual death rate due to lightning, per head of population, in states like Florida? Do you keep statistics?

How does it compare with the death rate from being chewed to death by alligators in Florida swamps? Or dying from rattlesnake bites in Arizona? Does lightning make it to the newspapers?

Reg.

I think most of us choose to ignore risks that are beyond our perceived control. We have some pretty violent storm activity in the area I live (central North Carolina) but death and structure damage seem to be rare. Most of the time the human body represents a higher impedance path than its surroundings.

On the other hand, electronic property damage is common. It seems to go with certain locations. I live in one of those locations and I have taken all of the precautions I can think of over the winter months. We have had a couple of storms in the past week without noticeable damage. I am certain that the house took a hit on Saturday morning on the new lightning rod system at the east end of the structure. It sounded different than the usual damaging strike. It was more of a drawn out event (half a second or so) than the damaging explosive sound. I am speculating of course.

Last night a less threatening storm came through with no damage noted. However I have two Labrador Retriever dogs, "Shadow" an 85 pound black female that is especially smart, and "Bear" 130 pounds of white macho male. Shadow always takes refuge in the bath tub and Bear gets as close to me as he can for a storm. Last night I spent two hours on the floor comforting Bear during the storm and wondering if the dogs might simply be smarter than I!

I have had strikes in the past that resulted in "fireballs" bouncing through the room. The dogs came by the fear as a result.

IMHO, the difference between bravery and stupidity is how you choose to perceive it!

On a more positive note, I worked Italy, Spain, Wales and Poland on 20 meters yesterday afternoon with my new TenTec Jupiter transceiver. I believe this little ridge is a very good radio location...

Lightening deaths are part of the Darwin Award system. A group of
lawyers were fishing in a row-boat when a storm came up. One raised
his fishing pole and shouted, "Alright, God, take your best shot!"
They buried him shortly afterwards.

Lightening dangers are taught in schools from pre-school through high
school. Most people know that when lightening is in the area, to get
to cover, therefore, there is a lack of fatalities. However, there
are some caught unaware as lightening can precede a storm by as much
as 10-15 miles and some people don't realize that and stay vulnerable.

Lightening deaths are reported, but I don't think they will ever make
the national news unless it is a celebrity or at some really
prestigious event.

A often faulty memory seems to recall that lightning deaths in the USA
are generally around 75/year and several hundred injured. Mostly, these
occur at outdoor events such as picnics, barbecues, ball games, etc.

As is stated in another response: if you can't control it we tend to
ignore it.

Reg:

Every year there are a few reports of people struck by and often killed by lightning.

Indeed Florida is the leading place in the whole world for lightning activity and lightning deaths.

In Florida we have really vicious thunderstorm activity throughout the summer months. These storms come up fast, thunderheads rising upwards of 50,000 feet, with black wall clouds decending to ground level and the air thick with static and rain so hard that you cannot see more than 25 feet. Impressive stuff!

I have never personally met anyone who was struck by lightning.

One of my own [arbitrary length] dipoles was simply vaporized by a strike when I was not at home... the ladder line that fed it's center was also missing and there was a two foot diameter hole about a foot deep in the lawn where I had left the end of the line laying on the ground. That's where I place the ladder line when not in the shack. When I returned home after that storm, I found the rope ends at the two supports simply swinging in the wind with the insulators on the ends still intact. During the annual ARRL Field Day event, held at the peak of Florida lightning season, in June of each year, I/we quickly disconnect feedlines and throw them well away from the transmitter sites during thunderstorm approach, on several occasions during those Field Days, and from a distance and under appropriate shelter, I have personally watched arcs jumping across the air gap between the conductors of the end of ladder line lying on the ground during the passage of thunderclouds. But I have never witnessed an actual strike on one of those antennas.

I don't have statistics at hand, but I can relay that most of the news reports of lightning deaths that I recall here in Florida were of the deaths of unfortunate golfers who failed to take shelter during a thunderstorm approach. I do recall a news report of someone killed by lightning on a Florida beach within the past couple of years.

It would be my guess that most who are struck by lightning in Florida are visitors... As far as I can tell, most folks who live in Florida year round are very well aware of the dangers of lightning and take appropriate cautions.

I guess my conclusion is that the conventional J-Pole design seems to be more susceptible to near by objects than the much less common end fed, open stub, J-Pole. My conventional copper J-pole changed much more than the end fed Arrow J-Pole when moved from the basement to the attic. And I have noticed on other occasions that even very small changes in location and/or orientation had a large effect on SWR.

The ARRL Antenna Book has a small section on J-Pole antennas. They show both designs, conventional shorted stub and the uncommon end fed, open stub designs. They say that the shorted stub design should have a 4/1 balun at the feed point because a direct coax connection results in extreme sensitivity to near by objects. And they also say the end fed, open stub design doesn't require a balun and is much less sensitive to near by objects, but is harder to tune. (I don't understand that point, there is one less parameter to fiddle with.)

All of this leads me to wonder why almost all J-Pole designs one sees are of the shorted stub version and almost none use a balun. I suspect ease of construction and low cost. My "store bought" Arrow end fed, open stub, J-Pole seems to verify the ARRL Antenna Book's conclusions about sensitivity to near by objects. However, do-it-yourself construction does appear to be much more difficult. I may give it a try, just out of curiosity.

A final note. My attic is a very difficult place to work. There is no way I can install an antenna and then make numerous adjustments to get it tuned to the space. I must be able to do any required tuning in my basement shop or maybe outside on my deck and then take it to the attic for installation. So for my application, I want something that is not sensitive to near by objects. The end fed, open stub J-Pole seems to fit that requirement.

[snip]

A j-pole (open or closed stub) will perform better with a common mode
choke at the feed point. Even better, use two chokes. One at the feed
point and the other 1/4-wave down the line.

This will reduce the higher angle radiation that results from the feed
line being part of the antenna.

Using a choke on ANY antenna fed with coax is just good engineering
practice. It can't hurt - only help. A few turns of coax costs very
little.

Hi Tom:

Hmmm... Thunderclouds, lumped or distributed? It all depends upon the application requirments... if the occurence is infrequent one may make a quasi-static assumption and invoke DC conditions.

Then we can make an approximation and treat the lightning stroke just as a DC conductor.

Now... Just what is the steady state DC value for a lightning stroke?

Ignoring the parasitic capacitance between strokes... we can approximate it as a long vertical wire, without loading...

Then...

Well you get the picture [grin].

Incidently we are in a very unusual dry spell here on the barrier island off Florida's East coast... we have only had about 1/8 inch of rain in the past three months, and the whole County is on fire!

Regards,

Roy, W7EL wrote:
"What is the velocity factor, and how did you calculate it?"

Given:
length = 12 inches
diamwter = 6 in.
L = 38.6 microhenry

I used formula (37) from Terman`s Handbook to calculate 25 turns in the coil. 471 inches of wire are needed in the coil.

The velocity of the EM wave traveling around the turns of the coil is almost equal to the velocity in a straight wire. But, the time required to travel 471 inches is 40 times the time required to travel 12 inches. The velocity factor is the reciprocal of 40 or 0.025.

Best regards, Richard Harrison, KB5WZI

It was a technical question. I was just wondering what keeps
the wire from transferring energy when it is located in free
space.

> What's it's velocity factor, and how did you calculate it?

13.48 MHz is not exactly the self-resonant frequency of the
coil. At 13.48 MHz, the one foot bottom section is 0.0137
wavelengths long, i.e. 4.9 degrees. So the coil occupies
85.1 degrees, i.e. 0.236 wavelength. The coil length is
coincidentally also one foot so the velocity factor is
4.9/85.1 = 0.058.

13.48 MHz is not exactly the self-resonant frequency of the
coil. At 13.48 MHz, the one foot bottom section is 0.0137
wavelengths long, i.e. 4.9 degrees. So the coil occupies
~85.1 degrees at self-resonance. The coil length is coincidentally
also one foot so the velocity factor is 4.9/85.1 = 0.058.

I don't have the Terman Handbook. Does he take adjacent coil
coupling into account in that formula? If not, that's the
difference in the two results.

In either case, the velocity factor is not anywhere near 1.0
as the lumped circuit model would have us believe.

Does anyone have a formula for what percentage of current is
induced in coils farther and farther away from the primary
coil? I haven't found such a formula in my references but it's
got to exist.

Yes, I read Cebik's article on J-Poles several times. I don't doubt that both designs can be tuned to the same SWR and produce the same performance. And I tried the brass bolt and nut trick and a coil of coax at the feed point. But in my basement shop, the shorted stub copper J-Pole was very, very sensitive to almost any change of orientation or location. And then everything changed when I installed it in the attic. But the Arrow open stub J-Pole seemed to produce the same SWR regardless of orientation or location in my basement or in the attic.

Anyway, thanks for the insight, jimbo

I suspect that they're more correctly modelled as resonant circuits...
specifically, as quartz-crystal oscillators.

I keep hearing pilots talk about "clouds full of rocks"...

> DC conductor.

No!! A much better model is a capacitor arcing over. The current in the strike goes from zero to Imax [<100,000 amperes] in less than 1 microsecond. This is followed by a decaying current [approximate exponential decay] that reaches 'steady state' in several 10s of milliseconds. This is followed by an secondary exponential decay of up to 500 milliseconds at somewhere around 500 to 600 amperes [this is basically the sustaining or continuing channel current.

The static we hear is caused by the displacement current in the initial discharge. The bandwidth of the static is determined by the rise and fall times of the initial discharge characteristics.

>
> Now... Just what is the steady state DC value for a lightning stroke?

90% of all lightning strikes in the USA have a "continuing channel current" [long term channel current] of less than 600 amperes. It continues for less than 1 second.

What on earth made you think that hams are generally safety conscious?

From my experience, I suggest that most place little value on safety
(fire safety, electrical safety, safe working at heights, safe
vehicular installations, protecting immediate family and other would
be rescuers from risk in the event of an accident).

I am not saying that no one does it, just very few.

A walk around most amateur stations reveals uncontrolled hazards.

And the statistics say that the probability of adverse outcome is low.

So in an unconscious risk managed approach, it seems most people
assess that "it won't happen to me".

Owen

PS: there are standards or codes that relate to lightning and
electrical hazards in most modern jurisdictions, but amateurs seem
rarely familiar with them, and to the extent that there is any
compliance, it is entirely accidental and unintended.

Hmmm. Looks like ignorance is bliss, Reg. I would have human strikes
and kills to be much lower in the UK than it is. Unless I totally
misunderstand the weather patterns there vs. here, you couldn't possibly
get the number of severe thunderstorms that we do in the US. So maybe
we are more aware and better prepared.

Although I could be quite mistaken in my beliefs. But I doubt it.

With multi-hops through the ionosphere there will be reflections from the ground between adjacent hops. If there are N hops there will be N-1 ground reflections.

At each reflection a signal loss is incurred. But the ground is a variable quantity.

What rule of thumb relating to reflection loss is used by radio professionals when calculating path loss?

At the back of my mind I have a figure of 5 dB per reflection. Is this in the right ball park?

Thank you.

It has just occurred to me that the loss due to ground reflections may
be related to the angle at which waves strike the earth. It is the
same angle as the transmit elevation angle and can be quite small.

The amplitude and phase of a field after ground reflection depends on the polarization, and is quite different for horizontal and vertical. It of course also depends on ground conductivity and permittivity, frequency, and angle. The equations are simple, and can be found in Kraus and other references. Those equations are used by NEC for determination of the far field pattern.

Uh, uh,
Wait until Richard Clark sees this and descends on you!!! :-)

Reg,
you can't just look at HF waves propagation through simple "reflective" glasses. There is considerable amount of propagating going on by refraction, ducting, polarization gets all tumbled around and ground conditions vary so much that even those orderly, same current in a loading coil believers get drowned. There are some propagation prediction programs that will do some predicting +- 59%, but that's about it. Otherwise as W7EL says, if you are looking at the antenna pattern forming properties within few wavelengths you need to consider polarization and ground conditions within the zone, but once you get beyond "first hop" you are on the mercy of propagation Gods.
You can look at my oooold article
http://members.aol.com/ve3bmv/bmvpropagation.htm
which at the time was judged "ridiculous" and "nothing new" at the same time. Now a days, especially low band crowds are coming around and admitting that there is perhaps more refracting/ducting than reflecting going on and trying to figure out when, why, how.
W8JI fought another losing battle claiming that there is no high angle propagation on extreme DX signals on 160/80, or skewed path. Now he is "guru" on the subject.
Soooo, depends.... what you are after? For "regular" conditions you can apply some ballparks, but for extreme DXing and weak signal comms, there is whole different world outside of formulas.

It does deserve some praise, however this guy was not the first. At some point in my 45 years I have made contacts using a rain gutter, the metal tube in the center of my brick chimney, the metal fire escape outside my dorm room and on and on. If it was metal, and I needed an antenna, I tried it. I don't remember bed springs or a wet noodle, but that may be next.

Reflection loss can vary from zero to infinity; depending on the material
and angle of incidence.
For example; take the oblique incidence of a horizontally polarized EM wave
on an air/rocky
ground interface of:: conductivity 2 mS/m, and relative permittivity 15.
The reflection loss
at zero degrees is 4.4 dB, increasing to 21.4 dB at the pseudo Brewster
angle of 76 degrees, and
0 dB at 90 degrees. Ref. Advanced Engineering Electromagnetics, C. A.
Balanis, pp 206 - 214.
I have copies of the Mathcad calculations if anybody is interested.

Frank

Reg, G4FGQ wrote:
"At the back of my mind I have a figure of 5 dB per reflection. Is this the right ball park?"

It could be right for some reflections.

E.A. Laport was Chief Engineer of RCA International when he wrote "Radio Antenna Engineering". On page 236 Fig. 3.17 shows the effect of ground conductivity on maximum field strength from a horizontal dipole antenna versus its height in vavelengths.

Optimum height would be about 0,50 wavelength to most concentrate energy at a certain vertical angle, 30-degrees according to the RAF Signal Manual quoted by Laport. 30-degrees might hop 1000 kilometers.

At the antenna earth reflection point, frequencies between 2 and 16 MHz are reduced to 95% of their prereflection field strengths by ordinary soil from a dipole at 1/2-wavelength height. A reduction to 70.7% of prereflection strength would represent a 3 dB power loss. So no harm done yet by the reflection from an antenna over good soil. Lower antenna height and poorer soil would attenuate more.

The angle at which rhe signal strikes the earth in subsequent reflections should be the same as the first reflection from the antenna. Conductivity and dielectric constant at subsequent earth reflection points are what they are.

Shortwave broadcasters use vertically stacked horizontal elements to concentrate the vertical beam to avoid multipath interference. They also prefer targets reached on the first reflection from the ionosphere..

Yes I know. That's obvious.

But what I would like to know is a typical or average value, or a
range of most likely expected values found in practice. Some
experienced person must know!

Needed to crudely ESTIMATE ionospheric multi-hop path loss.

Ground reflection losses are a small proportion of the total path loss
but not small enough to be neglected.

Just a whole number of decibels per reflection will do please.

Reg.

Some approximate examples at 7 MHz with angles of incidence
from 0 - 40 degrees:

Sea Water 0.2 dB
Rocky Ground 5 dB
Average Gnd. 2 dB

Why? There's nothing unusual or exceptional about it.

I used one successfully on 80 meters for a number of years from an apartment in Denver. And when I was a kid my main 20 meter antenna was an approximately half wavelength of #28 enamled wire slammed in my window and running to a clothesline pole in the back yard. Insulator was a plastic curtain ring. Worked lots of stateside stations from Alaska with a homebrew 6L6 rig -- probably about 10 watts output.

I've worked JA on 40 meter CW with a base loaded CB whip from a VW squareback and about 8 watts, and Alaska from Denver (good signal report on SSB) with 50 watts using a dipole strung around a basement. I worked New Hebrides on 40 meters with a bent attic dipole 16 feet above ground, (#28 hookup wire stapled to the eave) and running 1.5 watts. Solid copy, and I got a QSL. A rain gutter probably would have done better.

Anyone who's been a ham for a few years probably has a handful of similar stories. What conclusions should we draw from them?

Not quite what I was expecting, but let's see if I understand what it means. This means that if we put a current into one end of the inductor, it'll take about 40 ns for current to reach the other end, right? So we should expect a phase delay in the current of 180 degrees at 6.15 MHz, or about 30 degrees at 1 MHz, from one end to the other?

Message-ID: <ak725296eea9g6rjnerrqu9ta0to2suh8v@4ax.com>
Source record: 60300

I have a Cushcraft A3S Beam on a tower. It does not currently have a lightning arrestor on the feed line and is working well. The feed arrangement is center conductor to one side of the driven element, shield to the other side. There is a coil of coax at the top as a choke. This leaves the elements and the coax ungrounded. I have relied entirely on disconnecting the antenna for protection. when not in use. I would like to put an arrestor in the line but recommendations are sketchy even from those who sell them. I assume it would be most effective at the base of the tower on the ground rod. The drawing in the ARRL Antenna Handbook shows the arrestor on a common station ground.

Comments & opinions please...

Ionospherically reflected radio waves really do "want" to propagate, in spite of compromised antennas.

About 40 years ago while running an old Knight Kit T-150 on 80 m cw, I had a few 100 mw of spur on 5.525 mhz. I got a QSL card from the FCC telling me that the Canadian's were not too happy with me, and could I please fix things. Rotten antenna, low power output, and I still got a QSL card.

Source record: 60302

Thank you Richard, and the others, for digging out and presenting the information from which I can deduce a ball-park figure.

My original figure of 5 dB per hop for a ground reflection was slightly too high. It's nearer to 3.5 dB. I'm still thinking about it. But 4 dB is near enough. Not that it matters very much.

I deduced 5 dB from my experience of signal strengths received from such places as the antipodes and the Western US states. It's not surprising hopping across just the North Atlantic results in zero dB loss.

The excess path loss, over and above spreading loss, must be due to ground reflection losses. Just calculate backwards from received signal strength, path distance and the probable number of hops.

It's easy to do this with dedicated computer programs.

For very long distance paths assume that half the ground reflections are due to sea/ocean water and the other half is due to land masses and you won't go far wrong. Ground reflection losses at the transmitting and receiving sites can be ignored. Or such losses can be lumped together to constitute another complete hop.

I needed the information to include in a simple program which predicts (approximately) path loss for multi-hop propagation. Program users cannot be expected to know incidence angles, ground conductivity and permittivity, Brewster angles etc, for every hop along a route. Some guesswork is needed on the part of the programmer to make a program useful.

Despite your continuing abuse of the English language I know you are quite capable of understanding the foregoing waffle.

I'm on South Eastern Australian Merlot tonight. Hic!

I think the Chinese will be coming along shortly with their own high quality stuff. They are not just becoming adept with their high technology. Californian wine growers should look to their laurels. But no doubt you are all more immediately concerned with the price of oil, the gas in your tanks, and from where it may be obtained. Iraq and Iran for example.

1561. Missing Degrees in Mobile Antennas?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-04-27 20:28:12 UTC
From: Cecil Moore <mycall@arrl.net>
Message-ID: <wP94g.76939$dW3.71257@newssvr21.news.prodigy.com>
Source record: 60303

There seems to be an assumption by some posters here that
a mobile antenna must be electrically 90 degrees in length.
Here's a simple transmission line example to illustrate why
that is not true in the case of a loading coil used with straight
sections of antenna. In the following example, all transmission
lines are lossless.

We want to build a stub that is electrically 90 degrees long,
i.e. a 1/4WL open-circuited stub. The impedance at the
mouth of the 1/4WL open-circuited stub will be 0-j0 ohms,
a short circuit. The first stage of the stub is made from
Z0=450 ohm transmission line and is 30 degrees long.

0-j0 ----30 deg of 450 ohm line----+----50 ohm line---open-circuit

The question is: How many degrees of 50 ohm line do we need
to add to get 1/4WL in all. Sounds simple, huh? Just add 60
degrees and we will have our stub. But that is NOT what happens.

The impedance at '+' is -j259 ohms. That is -j.0575 on the 450 ohm
Smith Chart but is -j5.175 on the 50 ohm Smith Chart. So it takes
only 11 degrees of 50 ohm line to replace the function of 60
degrees of 450 ohm line. Want to stuff 90 degrees of function into
a 41 degree long stub? Make it a two-stage stub as above and
take advantage of the impedance discontinuity.

There is 60 degrees between -j0.575 and infinity on a Smith Chart.

There is 11 degrees between -j5.175 and infinity on a Smith Chart.

The Z01/Z02 impedance discontinuity has provided the "missing"
49 degrees of the stub.

The stub is only 41 degrees in physical length yet it functions
just like a 90 degree stub.

The same thing holds true for mobile antennas with loading coils.
The difference between the Z0 of the straight section and the Z0
of the loading coil provides the "missing" degrees of the antenna.
There is no requirement that the antenna be physically 90 degrees
long. There is no requirement that the delay through the coil plus
the delay through the straight sections add up to 90 degrees.
The impedance discontinuity provides the "missing" number of
degrees.

Two options:
#1 Unplug when not in use
#2 Throw it out the window after it's unplugged!!

Guiding logic: Lightning is better outside the shack than inside the shack. :-)

That 44dB down from S9+20 is still well above the noise floor :-)

I've made contacts with all sorts of random pieces of conductor too.
First stealth apartment antenna was a copper tape stick-on fed against
the balcony rail.

I much prefer 100 feet of magnet wire in the clear.

To that I very much prefer what my parents let me put up in the yard
when I was in high school and college: 28 foot tube tower with an A3S,
full wave rotatable loop for 17, 2el yagi for 12, 1/4 wave groundplane
(full size) for 40, sloping dipole for 30 and an 80m inverted vee.

So far I've not used an actual rain gutter or downspout, but I did
model one downspout into my shortened vertical dipole design on 40...
it's not an *intentional* part of the antenna :-)

I think it's great to get on the air with whatever you can. My goal is
to optimize my ability to radiate a signal given the limitations of my
site, and modeling and tweaking is a big part of that. I'm trying to
DX from an apartment complex though, so a handful of dB here and there
really matter.

I didn't quite get the invisible 5 element 20m monobander up to work
VU4 tho ;-)

FWIW, tau=sqrt(L*C); Z0=sqrt(L/C); L=3.86e-5; tau=4e-8
(Please note: That is NOT!! a lumped model!)

implies that C= 41pF and Z0=965ohms

(v.f. = 0.058 is left as an exercise for the reader.)

But if the coil's axis is parallel to a ground plane, that 6" diameter coil must be spaced about a quarter inch away from the ground plane (axis 3.25" from ground plane) to get that 41pF capacitance, and that's assuming a solid tube 3" in radius as a quick model .(An approximation!)

Cheers,
Tom

Hopper`s rule is one foot traveled per nanosecond. 40 feet of wire takes 40 nanoseconds.

The wavelength of 6.15 MHz is 48,8 or about 160 feet and in that space the phase rotates 360-degrees. 40 feet is 1/4 of 360-degrees or 90-degrees at 6.15 MHz. At 1 MHz, the wavelength is 300 meters. 12,2 meters of wire is about 15-degrees of delay by my $1-dollar Chinese calculator.

Thanks Frank,

Your figures for 7 MHz are representative of HF.

Nobody is particularly interested in MF, LF or VLF.

They confirm my latest estimate of an average, between sea water and
dry land, of roughly 3.5 dB per ground reflection.

Reg.

Sorry, my mistake. So let me rephrase my question:

This means that if we put a current into one end of the inductor, it'll take about 40 ns for current to reach the other end, right? So we should expect a phase delay in the current of 90 degrees at 6.15 MHz, or about 15 degrees at 1 MHz, from one end to the other?

Indeed.

Whilst it might have, and is probably still often done, it is unlikely
to comply with limits on Maximum Permitted Exposure to EMR. It has a
host of other disadvantages (EMC incompatibility, TVI/RFI, unreliable
performance to name a few).

The configuration is known as a CIA Special down here, being a covert
antenna. I suppose it is commonly done in places where covenants
prohibit external antennas.

...

You should be able to tweak the antenna on the bench until the SWR is more like 1.15:1 or so. Once you get it right there will probably be a lot less detuning once it is put in the attic

I've run the max permitted exposure calculators on some of my more egregiously located antennas, and you'd be surprised what it takes to exceed the limits if you're running 100W SSB. I've got to be in compliance for people on adjacent balconies, and it's pretty easy on HF.

According to http://n5xu.ae.utexas.edu/rfsafety/

Using 20% duty cycle for SSB to calculate average power of 20W into a 2.2dBi gain antenna (a pretty good rain gutter) at 7MHz, your neighbor has to be a whopping 1.46 feet from the antenna. You only have to be 0.86 feet away.

It is a good point that the stealth crowd should be checking these things out, though, as at least the apartment crew are using their antennas in densely packed quarters.

I have discovered from said site that I should not run 100W 6m RTTY into my Moxon lest the balcony next door become a more-than-allowed uncontrolled exposure zone. On the other hand, maybe that's a handy use for 25dB front to back ;-)

Not at all. Those whose performance criteria are limited to the binary categories of "works" and "doesn't work" are free to put the boundary between the two anywhere they want. It is rather entertaining, I have to admit, listening to two such people argue about antennas when the two have chosen very different boundaries.

Smith did not invent the Smith Chart. He simplified, for HF use only, charts which had been in existence since the Victorian Age, which covered all transmission line frequenies down to telephone and power frequencies.

You should be warned against using Smith Charts at frequencies less than about 1.5 or 2 MHz. Errors can be introduced of which you may be unaware.

On the other hand, at higher frequencies, the Smith Chart is an accurate time saver when making ordinary engineering transmission line calculations.

But now very much superceded by small computer programs which exceed the Smith Chart in both user time and accuracy,
----

>the ARRL Antenna Handbook shows the arrestor on a common station
>ground.

Once you have more than one or two antennas, disconnecting the feedlines
and throwing them out the window gets to be a real pain.

you probably want to

a) ground the shield of the coax at the base of the tower, and
b) have a lightning arrestor where the coax enters the house or at
your shack, and
c) connect the grounds of the tower, shack, and power co. together

I ground the coax shields at the base of my towers, run the coax
underground to the house, and then have lightning arrestors at the
house before the coax goes up to the shack on the 2nd story.

Dan, the greater issue here is the interpretation of of whether the radiator is accessible to members of the general public. If the kids next door come into the yard to retrieve their ball, it may be considered that it is accessible to the general public. Occupants of the premises (eg the rest of the family and visitors) may be considered to be the general public.

My first winter in Vermont in 1985 had me wanting to get back on the air. So much snow and no antennas. Then I realized that my wood stove was sitting on brick hearth in the living room and the of the chimney outside above the roof was in the neighborhood of 32 - 33 feet. I feed the RF through coax to the foot of the wood stove and worked my fair share of DX. Beam went yp soon thereafter.

No problem Reg. I did the computations recently trying to estimate the path loss, on 7 MHz,
from the west coast to Europe via the long path. The various ground losses from all kinds of ground, including polar ice, and fresh water, are all fairly low. The real problem was to estimate the losses due to the incidence with the diffuse, conductive, ionospheric plasmas, and also to consider
the possibility that some inonospheric ducting occurs. So far I have not attempted to estimate these losses, but they must be very high, since only considering ground incidence produces unrealistically
low path losses.

No, in the case of a base-loaded antenna, the "missing"
degrees are filled in at the impedance discontinuity
between the coil and the stinger.

Calif. agency OKs broadband via power lines test
Thu Apr 27, 2006 2:32 PM ET

SAN FRANCISCO (Reuters) - The California Public Utilities Commission approved a plan on Thursday allowing providers of high-speed Internet services to test using electricity lines to deliver online access throughout the state.

CPUC commissioner Rachelle Chong, who drafted the plan, said broadband over power lines, or BPL, could become a new competitor to Internet services delivered via telephone, cable and satellites and help reduce prices for consumers.

BPL uses existing utility lines delivering power to neighborhoods to carry broadband signals into homes.

It has been touted by equipment makers and regulators as a possible competitor to cable and telecommunications services, which handle almost all of the roughly 40 million U.S. residential broadband connections.

The regulatory commission adopted guidelines for electric utilities and companies that wish to develop and test projects in California.

Among the guidelines, electric utility affiliates and other developers can invest in and operate BPL systems.

Utility affiliates would have to follow CPUC rules for transactions between a utility and a BPL affiliate to protect against cross-subsidies, the commission said.

It depends on the plastic material - it's worth doing the microwave oven
test before using it. I find that PVC that's OK in the microwave oven
usually stands up to UV well.

That is not quite correct, what Smith did was to take to concept of the pre-existing equations and a rectangular chart which covered a limited range of impedances and develop them into a circular, more complex chart, that covered a full range of impedances. See the Introduction to Smith's book "Electronic Applications of the Smith Chart".

That's interesting. I believe carbon is sometimes added to plastics to improve UV resistance, and it would surely increase the loss at microwave frequencies. And many plastics like clear polyethylene are excellent low loss materials and won't heat in a microwave oven, but deteriorate rapidly in sunlight.

Are you sure the correlation between microwave results and UV resistance isn't just a coincidence of the materials you happen to have tested -- sort of like having an accident just after a black cat crosses your path?

==========
To be UV resistant the plastic should be black ,eg it contains carbon
black (like soot) If ,in general, plastic material is exposed to sun
light it deteriorates over time (especially when pigments are involved).
Example: coloured polypropylene rope .
If that material would be black ,it would have a very long life.
But then the sales of this material would decline ;)), hence you only
find coloured polypropylene rope ,blue ,orange ,red , yellow ,etc ,at
least in the UK.

Here in the north of Scotland (no sun in abundance) I use
(blue)polypropylene guys on a 13m (40ft)mast ,which have to be replaced
every 7 -8 years .But it is cheap.
Polyester rope as used on sailing boats is UV resistant (even without
carbon black) and would last 30+ years ,but it is relatively expensive.

Plastic antenna insulators (sold in the UK) are usually black , so are
the outdoor balun enclosures and plastic insulators on Yagi antennes.

In the 1960-70s when industrial instrumentation and control equipment
was predominantly pneumatic , coloured (polyethylene) tubing was often
used to identify types of signals in (indoor) control rooms . But since
lighting was often by fluorescent tubes , their UV radiation caused the
tubing to deteriorate and crack.
When it became a common problem an American company Samuel Moore then
produced black tubing with coloured stripes, solving the UV triggered
problem.

> And that differs from your bugcatcher how?

The whole point is that it doesn't differ.
That's how my bugcatcher works.

Here are the three parts to the answer.

1. The base-loading coil furnishes a delay equal to
a certain number of degrees which is nowhere near zero
degrees. Half of a coil self-resonant at 4 MHz would
provide 45 degrees of shift.

2. Using EZNEC to add a stinger to resonate the antenna
on 4 MHz, I find that's 11.5 degrees of straight element.
45 degrees plus 11.5 degrees is 56.5 degrees.

3. 90 - 56.5 = 33.5 degrees which is the "missing"
degrees filled in by the impedance discontinuity.
We can even estimate the ratio of the Z0 of the coil
to the Z0 of the stinger to be 5.0.

>>>There seems to be an assumption by some posters here that
>>>a mobile antenna must be electrically 90 degrees in length.
>>

Must be? Must is only death and taxes!

Resonant monopole must be 90 electrical degrees and resonant dipole must be 180 electrical degrees long. But that "must" does not apply to antennas as chosen by users. You can use light bulb, screwdriver, bedsprings, wet noodle or any piece of RF conducting material of any length, shape you like, just question how good of antenna it is.

We used 90 deg. monopole in discussion to show typical loaded or mobile antenna in order to avoid detours to la-la land (cases when current can be and is equal) and to stay on the subject of current magnitude along the typical loading coil.

Take a look at the rest of the posting, Yuri. I show where a
1/4WL stub can be made up of 30 degrees of 450 ohm line plus
11 degrees of 50 ohm line. The impedance discontinuity (at
a point) furnishes the "missing" 49 degrees of stub.

At 4 MHz, that would make a 1/4WL stub only 23.4 ft long
or about 10% of a wavelength instead of 25%.

Has anything been published on using multiple Z0's to
shorten the physical length of a stub?

1603. TT-247 and 102 whip for mobile antenna ?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-04-28 14:53:33 UTC
From: Buck <not@this.time>
Message-ID: <6na4521tmlo4ipifhhgo0u5dvt43t3l25c@4ax.com>
Source record: 60395

I have a TenTec 247 manual antenna tuner. I am thinking about installing a roof-mount over the space between the driver and passenger in the front of my mini-van and hanging my TT tuner below it. I understand the combination with automatic tuners works well, but I have been warned against using the TT to tune short antennas on low frequencies. Of course, this was in reference to dipoles and base antennas. The problem is reportedly that the loading coil will heat up and be damaged and have to be re-wound.

I have about a 2 foot extension that I may also use to extend the antenna a little.

I don't have the money to spend on auto-tuners and I have everything but the whip and mount for the antenna configuration I just described.

Cecil, W5DXP wrote:
"Dr. Corum`s VF equation predicts a VF of approximately double Richard`s----."

I wonder why? Dr. Terman wrote that the wave follows the turns in a coil. My recollection of common solid-dielectric coax VF is about 2/3 that of free-space due to the fense plastic.

Twice the velocity factor in a coil requires a wave traveling faster than light or taking a short-cut around the turns.

I often learn from my mistakes. Where did I err?

Best regards, Richard Harrison, KB5WZI

If there is a heating problem with a short dipole, there will be a heating problem with a 102" whip.

Some automatic tuners may do OK with the short whip. I think SGC does this, but if it works and is reasonably low-loss it is because the tuner is designed to do well with a short whip.

One way to make the tuner match a short whip better on low frequencies is to include a loading coil, in this case, at the base, to bring the antenna into resonance. The impedance of the antenna will then be a low resistive impedance, rather than a low resistive part and lots of capacitative reactance. The tuner will handle this better than the very short whip without a coil.

It seems to me that a short-whip automatic tuner should have an inductance in series with the antenna input, maybe a LCL tee network. I don't know what sort of topology the T-T 247 has but I don't think anyone is building an LCL tee manual antenna tuner. It'd be easy to do in an auto tuner though.

Anyone know the internals of the SGC short whip tuner (the one with the whip mounted to it)?

The newspapers and journals are full of information about warrantless wiretapping and eavesdropping. What many people do not realize is that the type of eavesdropping occurring for national security purposes is vastly different than the real world of eavesdropping and wiretapping utilized for industrial espionage, law enforcement and by your local private investigator or tech-guy that has crossed the line into illegal eavesdropping.

Now, the realistic world of eavesdropping has been thoroughly exposed in the new two-hour video called "The Red Balloon". Already recognized as the best Issue Awareness Video in 2005 at the international Aurora Awards and given a 5 Stars review in the March issue of Security Management, The Red Balloon presents the government and industry statistics about industrial espionage and eavesdropping, and how big this problem really is. It also reveals the different types of eavesdropping devices used with illegal wiretapping and eavesdropping and the novel techniques utilized by both professional and amateur eavesdroppers.

If you are curious about the eavesdropping industry then you simply must see the powerful informational video presented by one of the world's most recognized experts in the field. To learn more you can go to http://www.tscmvideo.com

In doing a bit of google searching for

short unloaded whip tuner

I've found some sources that say that the auto tuners tend to have a wider efficient matching range than the typical manual tuner.

So it may have nothing to do with network topology, it's just that if you can manage to match a very short unloaded whip with your typical manual tuner, you're going to be out at the edge of the matching range where it is quite inefficient.

What's the group experience with this? If it's true that the automatic tuners tend to be more efficient for a given range of impedances, what are likely reasons?

Can the typical auto tuner switch from LCL tee to CLC tee? Pi to Tee?

Is it always going to be better to use a binary switched inductor and capacitor system as opposed to a variable capacitor/tapped inductor system?

Maybe it's just that the latter usually gets shoved into a tiny box and the inductor Q is ruined?

Here's a simple transmission line example to illustrate why
that is not true in the case of a loading coil used with straight
sections of antenna. In the following example, all transmission
lines are lossless. ... 73, Cecil http://www.qsl.net/w5dxp

You guys sure like to go on-and-on starting with someones "rule of thumb" or catch phrase, taking either correct or not so correct math to prove or disprove what you may or may not already know...or just wave your flag in otheres faces. I guess my real point is that I see many uses of "electrical length" and "physical length" many of which are not used correctly. If the mental model(s) we have and are trying to use as a basis for a field of study don't quite work well enough to be useful most all the time, then they probably aren't correct. The best model is one that always applies when applied appropriately and you won't know what appropriate means unless you have a good model to base it on. I know this soulds like circular reasonong, but that's the way it works and the best way I can descxribe it.

I think "electrical length of a conbination of components" is a poor way to look at it and therefore a poor mental model to use. Bring in an uneeded term called "electrical length" or looking for the "missing degrees" is pretty much a red herring complication. I maintain that trying to fit an "electricall length" to such a combination helps none in the understanding.

You do the math, get the correct answer and you are done. You don't need an extra "name".

My point would be that "elecreical length" is only correctly applicable to _A_ single length of Transmisison line. trying to force it into every other situation is only causing confusion and I should rest my case here, but....
We need it because there is a velocity factor and therefore, the phisical length is no longer good enough for discussion. It is obvious that hooking up different lengths of different characteristic impedance transmisison line has a complex effect on what you wind up with and it is therefore inapropriate to use that specific terminology to describe the complex situation. I didn't check Cecil's math, but assuming he did it correctly, this is no surprise - it is expected as a result. However, have a need to ascribe a TOTAL "electrical length" based on individual "electrical lengths" of a complex combination of lines is inappropriate - not helpful for real

nunderstanding.
You might be inclined, and therefore properly understood, if you talk about the finished product in a slightly different mannor. If the phase angle and impedance is the same as you would have gotten with some (single hunk of) reference line, then you could say that it "appears equivalent to" a such-and-such line with an electrical length of X degrees, but the complex combinatin no longer has something we can rightly call an electrical length because it is not an _it_, but a _them_...if you get my drift.

You guys are going to use up all the words for the rest of us... (:-)

Is the purpose of this newsgroup to smear individuals or to
get to the technical facts? Nobody is 100% correct 100% of
the time. The coil still occupies tens of degrees and still
suffers a current taper because of that delay.

> It only took three or four years, but at least that's better than
> Fractenna. :-)

I wouldn't laugh just yet, Tom. There's plenty of misconceptions
on both sides. The delay through the loading coil is still tens of
degrees, not anywhere close to the near-zero degrees that you have
been asserting for years. The delay through a typical 75m bugcatcher
coil appears to be about ~35 degrees with ~11 degrees of stinger.
The "missing" ~44 degrees occurs at the impedance discontinuity
between the coil and the stinger just as it does in my 450/50 ohm
stub example.

The 3 nS delay measured by you and the undetectable delay
measured by W7EL were invalid measurements of delay.
Standing wave current suffers zero delay all along a 1/2WL
dipole whether it be in a wire or in a coil. The delay through a
typical mobile loading coil on 4 MHz appears to be about 25 nS
about half of what one would get in a straight wire equal to the
wire used in the coil.

1614. Wire diameter vs Impedance

Newsgroup: rec.radio.amateur.antenna
Date: 2006-04-28 16:31:42 UTC
From: Pierre Desjardins <pierred1@sympatico.ca>
Message-ID: <icg45291fio7hru744scc2jjioa5ik20m8@4ax.com>
Source record: 60407

Hi to all.. It is well know that a reduction in the diameter of the wire must be compensated by a higher antenna length to maintain resonance.

I am looking for an explanation of the reason for this. Why the total reactance becomes more capacitive? I know math formula showing the variation of the inductance of the wire vs its diameter, but I a looking for the real reason, not the mathematical consequence.

I suspect that a higher diam cause higher transormation of AC to electromagnetic energy on a segment delta(l) so that a shorter physical length would be needed to include the full electrical 180 degrees of a dipole.. but not really sure of this.

Any comment would be welcome

Thanks, and 73 de Pierre ve2pid

Source record: 60406

-- If you are unaware of the errors at low frequencies, it may well not make much difference whether you are using the Smith chart or not. Those errors may still bite you.

-- If your computer isn't powered up and you have a quick calc to do, the "small computer program" may very well far exceed the Smith chart in user time!

-- Though a program may provide more accurate calculations for the given input values than a Smith chart, it would be unusual that you KNOW the impedances, line lengths, inductances, etc. that you are working with to the accuracy to which they can be plotted on a decent-size Smith chart. It's easy to plot things to within 0.01 reflection coefficient units on such a chart, and it's very likely that the "50 ohm" coax you are using will be further away from 50 ohms than that. To quote some famous guru, 'Have you never heard of the word "approximation"?'

-- For those of us who appreciate that sort of graphical representation, a Smith chart can be a wonderful visualization tool. To me, that's its strongest point. Forget using it to DO the calculations; let a computer program or a vector network analyzer do the calcs or make the measurements. It's still worthwhile to me to have the results presented on the Smith chart overlay of complex reflection coefficient. (Note that a Smith chart is 'just' grid lines on top of a linear graph of reflection coefficient referenced to the normalization impedance you're using.) And of course it's useful for far more than just transmission lines.

For those who always have an appropriate calculating engine at hand and don't get anything out of a graphical representation of the results, toss the Smith chart out the window. But don't assume it's not still _very_ useful to those who see things easily from the graphics. Can YOU look at a table of 100 values of complex reflection coefficient versus frequency for a component and summarize them in your mind as rapidly as you can by looking at the same values plotted on a Smith chart? If you can, that's great. I can't. Thank you, Mr. Smith.

Cheers,
Tom

The current does take a short-cut due to adjacent coil coupling.
But please note the velocity factor only approximately doubles
from the "round and round the coil" calculation. Even though a
VF of 0.04 is ~double the "round and round the coil" approximation,
it is still 96% away from the VF=1.0 originally asserted by W8JI
which assumes that all the coils couple 100% to all the other coils.

Unless "they" can tie this to known antenna impedances, such claims
are worthless. And for another, what are the "typical" tuners that
are being compared to? Its easy enough to say what they are if it was
easy enough to measure them to support this claim.

>So it may have nothing to do with network topology, it's just that if
>you can manage to match a very short unloaded whip with your typical

Matching and effeciency are only distantly related. Using padding
resistors could pull any antenna into a match - not much efficiency
there.

>What's the group experience with this? If it's true that the automatic
>tuners tend to be more efficient for a given range of impedances, what
>are likely reasons?

There's a sucker born every minute?

>Can the typical auto tuner switch from LCL tee to CLC tee? Pi to Tee?

That would have seem to have answered itself if your survey of
different auto-tuners was useful. Barring these results being
obvious, it would seem you simply discovered the font of Marketing
hype.

>Is it always going to be better to use a binary switched inductor and
>capacitor system as opposed to a variable capacitor/tapped inductor
>system?

Depends on the granularity. Binary could mean one of two, or one of
1024.

>Maybe it's just that the latter usually gets shoved into a tiny box and
>the inductor Q is ruined?

For auto-tuners, that should be evident - and a marked counter to the
claim of greater efficiency.

Steve, I put "missing" in quotes because there is no missing part of
the antenna. I've been saying for months that a 75m mobile antenna
doesn't have to be 90 degrees long to be resonant. All that is
required is that (Vfor+Vref) be in phase with (Ifor+Iref) where
those are phasor additions. The real world phase shift accomplished
by an impedance discontinuity is caused by instantaneous interference
and doesn't require a delay. The basics of such an event are covered
in my '05 magazine article available at http://www.qsl.net/w5dxp/energy.htm

1620. Automatic tuner efficiency survey... from Re: TT-247 and 102 whip

Newsgroup: rec.radio.amateur.antenna

Richard, first I'll say that I did NOT find a survey, I've seen statements to this effect. (See http://www.eham.net/articles/4424) Of course, I've found statements to the contrary.

I'd like to collect some data points if people have actually measured the input and output power of their tuner into various loads, and I'll keep looking for real data.

I'd also like to focus my question about matching range and efficiency and retract all the other questions for now. I realize reading your response that I asked a bunch of general questions that were at best ill-defined an at worst trolly-sounding.

Pick a topology, let's say the shunt L tee (CLC) because it's so common. Assume your tuner (the one who tunes), human or microprocessor, is smart enough to select the most efficient values of C1, L and C2 if there happens to be more than one solution for a particular set of impedances.

Let's say I have a range of impedances within which I can get a 1:1 50 ohm SWR: How about the interior of the rectangle between 5 and 1000 ohms resistance, -500 to 500 ohms reactance.

Then take the subregion of that rectangle where efficiency of the tuner is greater than some value, say, 79.4% (so you're losing no more than 1dB in the tuner)

Here's one question:

Is that subregion really complicated, with lots of small spots where you can get an efficient match right next to spots where you're dumping lots of power into the tuner, or is the variation more smooth?

I'll leave it at that for now. I've got more questions that would pend knowing the answer to that one.

I may have to sit down with one of the CLC tuner simulators and make myself a plot.

Right on.

And another handy feature is the ability to see what elements of a
matching network are doing. Lines of constant Q drawn on the chart
can also keep one out of trouble.

I remember one thread about 3 years ago wherein someone (he knows who he is) stated that fewer matching elements -always- provide a lower loss solution than more elements do. A few minutes with a Smith chart with some constant Q circles and I found an example where that is not the case.

Try increased capacitance from larger wire diameter, larger surface (plate)
area.
Capacitance goes up, inductance (length) has to come down in order to
maintain resonance - LC circuit in standing wave environment.

Hi Pierre,

The total reactance before you shrank the wire diameter was balanced at zero (presuming a resonant structure). After the wire diameter was made smaller, for the same length, the inductance was lowered. Less inductance to balance the existing capacitance leaves an excess capacitance you observe. Of course, by making the wire thinner also changes capacitance, the change in inductance moved further.

Oh, Richard, Richard...

A smaller wire diameter has MORE inductance, not less, in the same environment. Think for a moment about coax: reduce the inner conductor diameter, and the impedance goes up while the propagation velocity stays the same. That means that C goes down and L goes up.

For Pierre: something else to ponder is that the change for resonance (zero reactance) in a half-wave dipole is considerably less than the change in a full-wave ("anti-resonant") dipole, for the same wire diameter change.

I don't think that simple concepts of the antenna behaving like a TEM transmission line are going to cut it here, and I'll wait for a better explanation than that.

Cheers,
Tom

I think I understand your intent. What I say is drop the following
sentence:

"I've been saying for months that a 75m mobile antenna
doesn't have to be 90 degrees long to be resonant.

Forget electrical length discussions in regard to anything but a single transmission line piece. I don't think it makes any improvement in understanding what is going on to add talk about something you want to call the electrical length of a complex system of lines and components. I think it adds unnecessary complication. My opinion is that this is taking a concept used in transmission line discussions and applying it where it is not needed.

Though I didn't verify your math on the original example, I don't find the type of result surprising and doing he math is all that is needed. I would not have expected that the "degrees" of electrical length to add up to 90, or whatever an equivalent antenna or t-line length would have been. I do understand the desire to form what I call a "mental model" which allows us to understand how things work so that we can use them. Lord knows that waves need some kind of help to get them into our minds so we can feel comfortable about how this all fits together. In fact, sometimes I get the impression these discussions become a battle between two mental models that may work for the individual posters, but don't fit into the other's model and many words ensue trying to pull each other over to the other's mental model paradigm.

Talk such as the following it sufficient. (although I'd have to think about the specific thing you say here since I don't think about transmission line things in those terms)

Yes, I did invert the relation of thickness to inductance - for a short wire. However, the feedpoint observation speaks of common results offering a different perspective. This is the question.

It does not intuitively follow to describe less capacitance for the same size, but now thinner antenna makes an antenna more capacitive, does it? [A transform is at work.]

>Think for a moment about coax: reduce the inner
>conductor diameter, and the impedance goes up while the propagation
>velocity stays the same.

This analogy begins to break down for antennas in that as the antenna grows thinner/thicker, the propagation velocity does change. On the other hand, and agreeing with your example, Z tracks (lower w/thicker) with an antenna. This is in conflict.

>That means that C goes down and L goes up.
with a proviso:
>I don't think that simple concepts of the antenna behaving like a TEM
>transmission line are going to cut it here, and I'll wait for a better
>explanation than that.

No, it didn't.

For an antenna with an with an element circumference of 0.001 wavelength, the Vf is 0.97 to 0.98. Compared to an antenna with an element circumference of 0.1 wavelength, the Vf is 0.78 to 0.79.

Velocity factor is a property of the capacitor's insulative medium (relative permittivity), which has never changed. [I would argue that the medium has in fact changed by the presence of the radiator, but that is another thread.]

Large structures near resonance confound small component analytical results. So, we will both wait for Reggie to explain it in what he calls english; or for Cecil to explode with a new SWR analysis.

From the IEEE Dictionary: "instantaneous - A qualifying term
indicating that no delay is purposely introduced in the action
of the device."

Does anyone have a formula for the coupling factor between
turns in a coil?

Source record: 60424

Thanks to all for the replies. I am considering building a few VHF and UHF yagi's for weak signal work and just kicking ideas around in my head. I was at Lowe's hardware the other day and spied the plastic drywall anchors. I took one from the package and over to the steel and aluminum rod isle and to my surprise one size of anchor was a PERFECT fit to 3/16" rod and another to 1/8".
The 1/8" (rod size) anchor even looks like the clamping ears (for lack of a better description) would extend and lock the anchor into place in a 1/16" or 3/32" antenna boom. If they can stand the rigors of the weather and have no detrimental effect at the frequencies being used, they look almost ideal!
I don't remember the color of the material but different sizes are different colors.
It might be interesting to throw a few in the microwave to see if they have any reactivity at even that high of a frequency. If they pass that test, I think I will build a yagi and see how long it last's. At worst, all I would have to do is replace them with Delrin in a year or two. I was hoping someone on here had tried it already but guess I get to be the guinea pig:-)
I will post later how it comes out.

Thanks,
RoD

I fell in love with his chart in my college days.

For my transmission lines courses we were offered the option of using the chart or doing the math. If we chose the chart, the only credit was for a correct answer. If we chose the math, we could get partial credit based on proper process. The exam was scheduled for 3 hours. Two of us left the exam room in 20 minutes with perfect scores on the final exam.

That was 48 years ago. I wish I could remember everything I've forgotten. Heck! I wish I could remember 10% of it!!!!

Source record: 60326

I'm going with Drs. Corum on this one. Solve equation 28 for tau, get beta from equation 4. The phase velocity along the axis of the coil is omega/beta.

The velocity factor in question is that phase velocity over the speed of light in a vacuum.

The coil modes are surface waves in a weird coordinate system. Note that the paper is very explicit in saying they're not TEM.

Throw equation 28 into Mathematica or Matlab or something and solve for tau. The cases given after equation 28 with all the limitations appear(ed?) to be a point of some contention, but equation 28 seems *only* to have the limitation of circumferential symmetry of the surface waves on the coil.

At the junctions between the wire and the coil, there is a transfer of energy between the surface wave modes on the coil and the usual antenna mode (I guess it's TEM?)

The coil is like G-line in that it guides surface waves, but the coil modes are modes specific to the helical geometry; the G-line surface waves are specific to the straight-wire geometry.

There is a mode on the helix where the waves go round and round the turns, but the example given is a traveling wave tube for microwave amplification, and it seems to me that there are a few turns over a few inches for *microwave* frequencies.

I am not one to argue with a solution to Maxwell's equations.

I need to proofread more. "At the junctions between the *ANTENNA* wire and the *LOADING* coil there is a transfer of energy..." would have been a bit clearer. Also very possibly inaccurate. The energy transfer may happen somewhere else in space as the fields around the antenna wire do not have the exponentially decaying radial behavior that the coil surface wave fields have.

I expect, though, that the current at the antenna wire/coil junction is what does the exciting of the surface wave modes on the helix.

Also should have said "a few turns over a few inches for a *TWT OPERATING* at microwave frequencies".

Not counting the potential tuner problems you mention, my experience is
a 102ï¿½ whip with no loading will work ok on 10-20m, but on 40m and below
it sucks.

>Richard Clark, KB7QHC

Thanks, Richard for the comments. I would like to use it for 75-6
meters as I am not worried about 160 meters. I would like to use it
on 75 meters, as it is the band most likely to meet the coverage I am
interested in, but also to operate all bands as I would like not to
change antennas all the time. I have loaded the 20 meter and 40 meter
antennas with it to see how it works on other bands, but they really
suck!. I don't know if it is the way they are wound or what, but
tuning the 20 for six works well, but not with other bands. Going
lower doesn't help.

As for the mobile vs base antennas, there may be some difference. The
problem occurs when using a quarter wave or shorter dipole. However,
a quarter wave vertical is a match! This is part of my questioning.
Also, the fact that the tuner will be virtually at the antenna rather
than the coax, may make some difference, although, technically, I
think the coax would lower the reflected power to the tuner.

The theory i was hearing was that the loading coil takes all the
missing length of antenna and heats up. I can't imagine auto-tuners
having as large a coil as this manual tuner. (It uses a wire wrapped
around a toroid of some sort.) I imagine an autotuner uses much
smaller inductors tied together thru relays.

I am trying to think of a type thurmometer that I could use that
wouldn't interact with the tuner to see if it heats up.

I will probably test the antenna this weekend if I can get the parts
and time....

I would expect it to suck on the lower bands. I am trying to figure out some form of loading that will be cheap and simple to use. I have a 40 meter whip and I guess I could add the 102 to the top for a stinger, but that would make for a long and weak (physically) antenna.

75 mobile sucks under the best of conditions. That much I know. I may have to settle for a 75/80 meter antenna option. I am trying to think of a way to add a base coil that may allow me to tune lower bands more easily without upsetting the higher bands. I don't want to tune the coil itself every time I change bands, but I wouldn't mind bypassing the coil on those times I would rather not tune 80/40. I am very interested in operating 60 meters mobile on a regular basis as well as 20 and up.

Don't forget the control wires for your antenna rotator. Seems like
all your antennas and control cable(s) entering the shack through
arrestors on grounded metal plate is the recommended method these
days.

You can find some good poop on lightning protection here:

Source record: 60336

May 1st 2006, Civil War Begins

On May 1st 2006 The "Great American Boycott" also known as the "Day without immigrants" is scheduled to occur. Participant's stated goals are a general strike, No Work, No School, No Sales, and No Buying. These people want to shut down individual cities, all across the nation, thereby impacting the country as a whole.
Make no mistake about it, this is not just simple protesting, protesting with the goal of causing financial harm is Economic Terrorism plain and simple - and those people who participate are economic terrorists.
By shutting down certain cities, or even portions of cities, these protestors will be :
Keeping children out of school,
Hampering the abilities of local law enforcement to enforce the law,
Hampering the abilities of first responders to respond to car accidents, fires, people having heart attacks, and hampering their ability to transport them to the hospital.
Hampering the abilities of local mass transit systems to operate properly.
Causing financial harm to local businesses iregardless of whether or not those businesses have harmed them, resulting in a nationwide economic impact.
Advocating the breaking of our laws by demanding, yes demanding, that illegal immigrants be given amnesty.

terï¿½rorï¿½ism -"The unlawful use or threatened use of force or violence by a person or an organized group against people or property with the intention of intimidating or coercing societies or governments, often for ideological or political reasons." - American Heritageï¿½ Dictionary of the English Language, Fourth Edition
How can you fight back?
Ensure that your children go to school, and stay there on this day.
Purposely go and buy products and services in those cities affected by the protestors - gas up your car, go see a movie, go grocery shopping, buy a little more than you would have any other day. Counter their 'protest' with a positive economic impact in those areas affected.
Perhaps you might also consider making a donation to those organizations seeking to secure our borders on this day as well. Show these terrorists that you can and will fight back!
While the current situation is one of mass irresponsible action, causing financial harm across the nation, it will inevitably escalate into violence and deaths if these sorts of activities continue.
Does this constitute a civil war? Perhaps not yet, but its clearly heading in that direction, this may just be the first battle.

Dan, N3OX wrote:
"Also should have said "a few turns over a few inches for a "TWT OPERATING" at microwave frequencies".

That`s interesting. John D. Kraus invented the axial-mode helix antenna after attending a lecture on traveling wave tubes given by a famous scientist visiting Ohio tate University. Kraus asked the visitor if he thought the helix could be used as an antenna. The visitor said no, so Kraus went home, wound seven turns one wavelength in circumference and discovered it made a sharp beam off the open end when he used a ground plane across the driven end. The story appears on page 222 of Hraus` 3rd edition of "Antennas".

Lenkurt described operation of the traveling wave tube in its August 1965 edition of the "Demodulator". Here is an excerpt:
"The signal to be amplified by the tube is coupled into the gun end of the helix. This RF signal travels as a surface wave around the turns of the helix, toward the collector, at about the velocity of light. The forward or axial velocity of the signal is slower, of course, because of the pitch and diameter of the helix. This forward movement of the wave is analogous to the travel of a finely threaded screw where many turns are required to drive it into position. The signal wave generates an axial electric field which travels with it along the longitudinal axis of the helix. This alternating electric field interacts or velocity modulates the electrons in the beam."

Terman`s description in the 1955 edition of "Electronic and Radio Engineering" starts on page 678 and is very similar to Lenkurt`s. i`d bet that it is more than coincidental.

Kraus says of his new helical antenna on page 223 of his 3rd edition of "Antennas":
"At a low frequency (helix circumference about lambda/2) there was almost a pure standing wave (VSWR goes to infinity) all along the helix (outgoing and reflected waves nearly equal) (Fig. 8-3a)--."

Surely an antenna loading coil resembles Kraus` low-frequency helix. It has an open-circuit whip producing a reflection into one end. The circumference is well below 1/2-wavelength, giving a current distribution such as shown in Fig. 8-3a for a frequency below the axial mode of operation.

Fig. 8-3c shows uniform outgoing and reflected currents over the middle section of the helix. Kraus` figures were produced from actual measurements.

Best regards, Richard Harrison, KB5WZI

Hi Buck,

All reports of short, mobile antennas on 80M generally cry crippled.
That is, unless, they are augmented by center loads under top hats a
dozen feet high or more. Even then, hardly remarkable unless you can
stand to be down 2 S-Units out the gate. For some, this knowledge is
a killer. For others who ignore it, they simply work those who can
hear them.

>but also to operate all bands as I would like not to

Well, again, you are short on details. These two antennas (I presume
you have introduced two more to the discussion) may be air cooled
resistors for all their qualities you suggest. You might find an
object lesson here.

>I don't know if it is the way they are wound or what, but

Mobile quarterwave dipole?

>However,
>a quarter wave vertical is a match! This is part of my questioning.

Aside from this being natural, what could the question be?

>Also, the fact that the tuner will be virtually at the antenna rather
>than the coax, may make some difference, although, technically, I
>think the coax would lower the reflected power to the tuner.

Many antennas are designed with a match external to them, but quite
close by. Why would this be detrimental? Even more, many antennas
are built with the match as part of them. They go by many names,

Gamma being one. Certainly nothing is lost in their use.

>The theory i was hearing was that the loading coil takes all the
>missing length of antenna and heats up.

Dare I say you can't trust everything you hear (read here)?

Myself, I taught RF communications in the Navy and had no trouble whatever with the concept that a coil replaces the electrical length missing in a short antenna. However, the Navy was never a slave to fashion nor strict interpretation in this matter, and it was enough to observe this quid-pro-quo as symbolic, and not literal.

> I can't imagine auto-tuners
>having as large a coil as this manual tuner. (It uses a wire wrapped

Indeed.

>I am trying to think of a type thurmometer that I could use that
>wouldn't interact with the tuner to see if it heats up.

Yuri might suggest aquarium thermometers (Liquid Crystal) - but you would have to make sure the entire surface fit the entire strip (or versa vice). If you have a very old digital camera, then they were sensitive to IR. You could take a picture in the dark and resolve hot spots.

>I will probably test the antenna this weekend if I can get the parts

So does this mean if we put a current into one end of the inductor I described, it'll take about 40 ns for current to reach the other end? So we should expect a phase delay in the current of 90 degrees at 6.15 MHz, or about 15 degrees at 1 MHz, from one end to the other?

What good are all these books if the information can't be used to solve a simple problem?

Source record: 60340

when the metal plates move and more surface is used/covered by the cap,
is the capacitance higherb (farads) ??

I see that with loop ant, the more the plates cover each other, the
lower the tuned freq is ...

So with a high cap, you could make an ant with less turns of wire ...

Sometimes I find a large cap (1 F) at flea markets, for 1 euro/$ or so.

They cost 100 or so new. Would they make sense ??

I realize this. I have used a Hustler on 75 before. I was definitely
a weak signal station. I can only imagine that a tuned whip would
generate similar results, or more likely, poorer results.

There are a total of four antennas I have mentioned in here for
comparison sake. The Hustler, just mentioned above, the 102 whip with
a possible 2 foot extension, and two Antenna Specialists (AS) (look
exactly like HamSticks). I haven't had the Hustler for over a decade.
I will introduce another antenna in this message later.

The AS antennas are thin fiberglass poles with long stingers on the
top. The fiberglass poles, of course, have copper wound around them
from bottom to top, above which is a whip (stinger) about the same
length as the pole. The hustler was a center loaded trap that was
several inches in diameter and about 10-12 inches tall (the trap part)
with a stinger on top. (You are probably familiar with the Hustler.)
I also have a Volvo brand CB whip. It is a thin fiberglass whip

similar to the bottom portions of the AS antennas, but it does not have a stinger. Like the AS antennas, the fiberglass has copper wire wound from bottom to top with the top tightly wound and the bottom section loosely wound. There is no stinger on top of the CB antenna.

I previously did a little experimenting with the two AS antennas and the Volvo CB antenna (I don't have the 102 whip yet.) I used the tuner to compare receive signals on various active bands. the results weren't very good. Basically, each antenna performed best on the frequencies for which they were designed (no big surprise here) but they performed terribly on any other band. In fact, they were not even acceptable for use on other bands. The signal strength on 20 meters, for example went from s-9 on the 20 AS antenna to less than s-2 on the other antennas. I know others who have used the 102 steel whip/auto-tuner combination that I have talked to never complained that they only received s-2 signals with the system. Therefore, my theory is that the winding of the coil on the fiberglass poles is adversely affecting the radiation on out-of-band operation. I am hoping that the steel whip, with or without the extension, will perform better on all bands than any of these antennas tested. I realize it is a compromise but the loss of an s-unit or two in exchange for all band coverage for my mobile without having to switch antennas or get out of the car and change taps is an acceptable trade-off.

Remember, too, that in the original post, money is a big issue. The purchase of a screwdriver (the best known mobile antenna design for all band coverage) is not an option at this time. My theory is that I should be able to mimic the 102 whip/auto-tuner results using a manual tuner. My question is whether or not the tuner itself can hold up to the task without being damaged.

>
>>I don't know if it is the way they are wound or what, but
>>tuning the 20 for six works well, but not with other bands. Going
>>lower doesn't help.
>
>Barring details....

I think I addressed that above, the fiberglass poles are wrapped tightly at the top and then loosely to the bottom, a stinger extends from the tops of the AS antennas, and the Volvo antenna doesn't have a stinger.

>
>>As for the mobile vs base antennas, there may be some difference. The
>>problem occurs when using a quarter wave or shorter dipole.
>
>Mobile quarterwave dipole?
base. The suggestion I was given was not to use the antenna tuner on a 20 meter dipole to tune a 40 meter frequency. This would be a 1/4 wave dipole on 40 meters. I don't know what the impedance of such an

antenna would be, but I do know that a 1/4 wave vertical is a
reasonable match. We never discussed the use of the tuner in the
mobile.

I should have clarified that this statement. The internal inductor of
the tuner makes up the missing length of the antenna and heats up
which can cause damage to the antenna tuner's inductor. This is how
it was presented to me, or how I understood it. Again, the discussion
was using the tuner to tune short dipoles to transmit on lower
frequencies.

I have been scheduled to work this weekend. I hope to be off Sunday,
If I can, I will try testing the whip idea using the side mount on the
van and if it appears to be promising, I will drill the holes in the
roof to mount the whip there near the radio and tuner.

I just re-read your statement. Are you saying the whip without a
loading coil used thru a tuner? My first thoughts were you meant
without a tuner.

I expect that 40 and below will be a bit poor. I hope to find a
compromise of sorts where I can add a loading coil, but only change it
when I want to operate 40-80 meters, sort of a switch between the
higher and lower bands as opposed to setting it for each band. The
alternative may be to have two antennas, one for the lower bands, set
as needed per band, and one for the upper bands that only needs tuning
with the tuner. If I am lucky, I may be able to have one with a
loading coil that tunes all the lower bands relatively efficiently and
the whip for the upper bands. I can deal with two antennas, I have a
switch but my problem right now is I have separate 40, 20, 11, 10, and
6 meter antennas. If I want to change bands, I have to replace each
antenna. Likewise, if I want to add a band, I have to buy more
antennas. I just want to simplify my operation for when I am mobile.
I have a 135 foot dipole with 300 ohm feed that I can toss up in the
trees for portable operation when I want to be efficient or for
emergency operations, but for moving, I don't want to pull off the
highway and get out of my car to change antennas every time I want to
change bands.

Thanks for the input.

SNIPPED

It is not terrorism per your quoted definition: "terï¿½rorï¿½ism -"The
UNLAWFUL [emphasis added] use or threatened use of force or violence ... "

I don't see any UNLAWFUL activity here. If you want a day off you take a
day off. If ten people want a day off, they take a day off. If 100
people want a day off, they take a day off. ...

The opening words of the USA Constitution are extremely important. "We
the PEOPLE ..." Note: it does not say Citizens.

The First Amendment to the USA Constitution states:
"Amendment I: Congress shall make no law respecting an establishment of
religion, or prohibiting the free exercise thereof; or abridging the
freedom of speech, or of the press; or the right of the people peaceably
to assemble, and to petition the government for a redress of grievances."

The protest is fully compliant with " freedom of speech", "peaceably to
assemble' and to "redress of grievances"

The Constitutional Rights you demand for yourself MUST be Rights for
those with whom you disagree.

1654. Re: question about caps in tuning loops ..

For transmitting purposes there is a high voltage across that capacitor.
I have a friend who uses 10,000 volts rated capacitors in a loop for 50
watts.

The 1 farad capacitors are generally very low voltage.

Equation (32) at http://www.ttr.com/TELSIKS2001-MASTER-1.pdf
answers that question. The VF is about double the "round and
round the coil" calculated value and the VF changes with
frequency.

> get to the technical facts?

I don't know. You and Yuri seem to be playing that game as much or more
than anyone else. It's tough for both sides to behave and anyone to
learn anything when all this strange stuff goes on, but this thread (in
various forms) is very similar to the famous Fractenna threads.

>Nobody is 100% correct 100% of
> the time.

....and that obviously includes you as well as the rest of us. The key
is to speak like friends and be honest rather than make this stuff
into a long "Fractenna" thread.

>The coil still occupies tens of degrees and still
> suffers a current taper because of that delay.

The coil does NOT have to occupy tens of degrees nor does it have to
provide any current phase delay from end to end. It does have to have
SOME delay and some current taper since it occupies space, but it can
be so small we can't reliably measure it.

The phase delay and current taper is tied to the load impedance on the
open end of the coil and the construction of the coil, not to the
electrical degrees. It appears you know that now.

> > It only took three or four years, but at least that's better than
> > Fractenna. :-)

> I wouldn't laugh just yet, Tom. There's plenty of misconceptions
> on both sides.

My opinion is Lewallen and maybe a dozen others have a good handle on
how it works. It appears you have gradually came more to center also,
but I'm not quite positive how far. At least you no longer apperar to
be saying the coil represents missing electrical degrees.

> The delay through the loading coil is still tens of
> degrees, not anywhere close to the near-zero degrees that you have
> been asserting for years.

Be careful there. I have NOT been asserting that for years. My initial assertions years ago was there was no delay, but that was because I considered the inductor an inductance and was speaking of an inductance. Over two or three years ago I posted this:

http://www.w8ji.com/mobile_and_loaded_antenna.htm

which explains it is a matter of stray capacitance to the outside world compared to load inmpedance terminating the coil that causes deviations from a "perfect" coil.

I also measured antenna current and posted the results at:

http://www.w8ji.com/mobile_antenna_current_measurements_at_w8ji.htm

>The delay through a typical 75m bugcatcher
> coil appears to be about ~35 degrees with ~11 degrees of stinger.
> The "missing" ~44 degrees occurs at the impedance discontinuity
> between the coil and the stinger just as it does in my 450/50 ohm
> stub example.

I'd bet money I can build a coil that has very low phase delay. I'd also bet I could build one with larger phase delay **at the same point and frequency in the same system**.

The problem is one of the stray capaciatnce from the coil to the outside world compared to terminating impedance of the coil.

> The 3 nS delay measured by you and the undetectable delay
> measured by W7EL were invalid measurements of delay.

So you say. We have only your opinion or view on that, and that dosagrees with other people's opinions. You are not the final word.

> Standing wave current suffers zero delay all along a 1/2WL
> dipole whether it be in a wire or in a coil. The delay through a
> typical mobile loading coil on 4 MHz appears to be about 25 nS
> about half of what one would get in a straight wire equal to the
> wire used in the coil.

Again it depends on the form factor of the coil. By altering the coil with no other changes it can be made to vary quite a bit.

Following are the summarized normalized combined results
of three 75m mobile antenna shootouts held in California
during the 1980's.

0 dB - (Reference) Bugcatcher or Screwdriver with large top hat

-2 dB - Bugcatcher or Screwdriver with no top hat

-5 dB - 8.5' whip with bugcatcher base loading coil

-6 dB - Bugcatcher with Stainless Steel Loading Coil

-8 dB - Hustler High Power system

-9 dB - Outbacker

-12 dB - Hamstick

-12 dB - 11.5' whip with SGC-230 autotuner

-14 dB - 8.5' whip with SGC-230 autotuner (estimated, not measured)

Source record: 60350

Not only what Dave wrote (that the voltage is likely to be too low),
but LOTS of other things too...
-- the RF losses of such a capacitor are often terrible
-- they are almost always polarized, not intended for use with an AC
signal but only as a filter for DC (especially one you'd pick up at a
flea market!)
-- I have some 1F 5.5V caps which are not so expensive new--but they
have very high series resistance. They are intended only as system
memory backup or similar for systems in which the backup current is low
microamps.
-- with such high capacitance, the loop would be so tiny that it would
be inefficient.
-- the self-resonant frequency of the capacitor is likly lower than the
frequency you want to tune the loop to. That means at the operating
frequency, the "capacitor" would look like an inductor and not tune the
loop anyway.
-- if you can manage to keep the losses low in the loop, even with a
reasonable tuning capacitance that you might actually be able to use,
the Q may be so high that the bandwidth is unuseably low.
-- the stability over temperature and time is terrible; the loop would
not stay tuned on one frequency.

These are broad generalizations. What you really need to do is look at
a SPECIFIC design and decide what capacitance makes sense from a system
performance standpoint. Will it be sensitive enough (as a receiving
loop)? Will it be efficient enough (as a transmitting loop)? Will the
bandwidth be large enough? Then the design will tell you what
capacitance you need, and you can ask the additional question: can I
tune it--how will I vary the tuning?

On very low frequencies, I can imagine using perhaps polypropylene caps
that are designed to work in switching power supplies and have low
inductance and low effective series resistance, but probably only for
use on one fixed frequency since changing the capacitance would be such
a hassle.

Assuming you're interested in low frequency receiving loops, have you
had a look at Reg's loop program? It can help you make decisions about
how to make your loop.

Cheers,
Tom

The low response to the question leads me to believe that many (most?)
have reached the same conclusions as I have.

That is:
Isolating the incoming antenna and control cables is the preferred
method. Providing a low impedance path to ground in the radio shack is
undesirable.

Further, adding an extra ground point in the system wherever is a
lightning no-no and introduces unknowns into the RF scheme. Especially
if one chooses to not run a 1:1 swr.

In my case the base of the tower has its own ground and is connected
to the structure lightning protection. I will continue to disconnect
and connect cables.

If an application that requires operation during electrical storms is
the norm, it becomes a different circumstance.

I will keep an open mind to the question though!

Same experience here, I grease eveything up with DC4 dielectric grease, not only does it keep the water out it acts like anti-sieze to make it come apert easy and wrap every thing in some good vinyl tape. One thing I have done a few times is to place some steel fishing leader under the tape. Whenever I want to open the splice just pull on the leader and it slices it open.

I still like to use heatshrink over the tape to give the tape some UV protection. I never trust heatshrik alone. I have had bad experience with this.

The coil has to obey the laws of physics. Most real-world
75m loading coils occupy tens of degrees of the mobile
antenna. Your assertion that nearly 100% of the coils link
nearly 100% of the total flux is unrealistic. The effect
of coil flux linkage approximately doubles the VF from
e.g. ~0.02 to ~0.04, not from 0.02 to near 1.0, as you
assert. A speed up by a factor of 2 is a lot more
realistic than a speed up by a factor of 50.

> The phase delay and current taper is tied to the load impedance on the
> open end of the coil and the construction of the coil, not to the
> electrical degrees.

Reference my stub example which contains *NO COIL*. There
is a *short circuit* looking into the stub.

---30 deg 450 ohm line---+---11 deg 50 ohm line---open

The 450 ohm line provides 30 deg of phase shift. The
impedance discontinuity at '+' provides 49 deg of
phase shift. The 50 ohm line provides 11 deg of phase
shift. All this happens without any coil in sight.

A very similar thing happens with a 75m mobile antenna.
The base loading coil provides tens of degrees of phase
shift. The impedance discontinuity between the coil and
the stinger provides tens of degrees of phase shift. The
stinger provides tens of degrees of phase shift.

You seem to have taken the tens of degrees of phase shift
in the coil and transferred those number of degrees to
the impedance discontinuity. That is a mistake based on
the presuppositions of the lumped circuit model.

Asserting such is akin to asserting that there is no delay
in the 450 ohm line section in the stub above.

> My opinion is Lewallen and maybe a dozen others have a good handle on
> how it works. It appears you have gradually came more to center also,
> but I'm not quite positive how far. At least you no longer appear to
> be saying the coil represents missing electrical degrees.

For months I have been saying that the mobile antenna doesn't
have to be 90 degrees long. It has been a couple of years
since I said that the coil represents missing electrical
degrees. You know that but still attempt through inuendo to
make hay from a mistake I made two years ago. I correct my
mistakes in real time. It doesn't matter what I said two
years ago. And you object when someone does that to you.

For months I have been saying that the coil delay is what it
is and nobody has made a valid measurement of that delay. The
best information available on that subject (to the best of
my knowledge) is Dr. Corum's paper at:

http://www.ttr.com/TELSIKS2001-MASTER-1.pdf

> I'd bet money I can build a coil that has very low phase delay. I'd
> also bet I could build one with larger phase delay **at the same point
> and frequency in the same system**.

We are not discussing how smart or tricky you can be in producing
one special case coil. We are discussing real-world 75m bugcatcher
coils. Whatever you assert has to apply to all coils, not one
special case. It doesn't matter that you can create one coil
that matches your assertions about all coils. That's like asserting
that all cars are white and producing one white car as proof.

> W5DXP wrote:

It's my view based on all the facts. If I'm wrong, I will freely
admit it and correct my misconceptions. However, at the present
time, I think I have proven that standing wave current on a
standing wave antenna cannot be used to measure the delay through
a wire, much less through a coil. You and W7EL both used standing
wave current, with its unchanging phase, in your phase measurements.

W7EL says that EZNEC agrees with me on that point. So he is in
the position of either disagreeing with EZNEC or admitting that
his phase measurements though accurate were meaningless. EZNEC
proves that standing wave current phase cannot be used to measure
phase shift through a wire, much less through a coil. As recently
as last month, you appeared not to know that fact as illustrated
by this previous posting.
****
> Cecil Moore wrote:
>> I made self-resonance measurements on loading coils

>>>> predicts -- constant along the wire.
****
W7EL agrees that the phase is "constant along the wire". How can a signal with constant phase be used to measure phase shift through a wire? or through a coil? After a year, there is still no answer provided for this technical question. The answer provided by EZNEC is at:

http://www.qsl.net/w5dxp/travstnd.GIF

>>Standing wave current suffers zero delay all along a 1/2WL
>>dipole whether it be in a wire or in a coil. The delay through a
>>typical mobile loading coil on 4 MHz appears to be about 25 nS
>>about half of what one would get in a straight wire equal to the
>>wire used in the coil.
>
> Again it depends on the form factor of the coil. By altering the coil
> with no other changes it can be made to vary quite a bit.

We are talking about 75m bugcatcher coils, Tom, not one special case coil engineered by you. If your assertions fail for a 75m bugcatcher coil, then they fail in reality. You assertions have to be valid for all cases or else they are invalid. Finding one special case that agrees with your assertions, e.g. your previous toroidal coil measurement, may boost your ego but doesn't really matter one iota in the overall scheme of technical fact.

Used various SGC tuners and Icom AH-4. Also tried both of SGCs dual loaded whips with varying results. The longer two piece unit worked surprisingly well 80-10m years ago when conditions were better, even had some fantastic 160m mobile contacts with it. The single 7ft version lacks on 40 and especially 80m compared to the two piece whip but compared to an unloaded 102ï¿½ CB whip, it makes the CB whip look like a dummy load on 40m and below. This is all with an SGC-230 feeding them.

FWIW, the latest paper catalog from RadioWorks shows adjustable
plexiglass inserts that will fit the bottom of any window, and they
will outfit the insert with feedthroughs for any type of coax or wire
plugs that you need.

Beware of academics who use phrases such as "anisotropically conducting cylindrical boundary," "helically disposed surface waveguide," and "voltage magnification by standing waves." These are just figures of speech. Some academics - fractenna comes to mind - get so carried away with their ideas, they'll try anything to justify them, including the use of nounspeak and polysyllabic jargon. Real scientists and engineers don't have to use such tactics to make a point.

Occupy 10's of degrees on 75 meters. Wavelength is about 250 feet. Each degree is .7 feet.

So you are saying the loading coil is "7's of feet long". Is that correct?

What's your point in making that switch? We were talking about loading coils, now you are switching to stubs. Why?

> A very similar thing happens with a 75m mobile antenna.
> The base loading coil provides tens of degrees of phase
> shift.

How do you know that?

I can prove that is wrong with measurements, and prove that the design of the coil as well as the placement as it affects stray capaciatncve can move that number all over the place.

I'm happy to see you no longer agree with the misplaced notion the coil replaces missing electrical degrees, but puzzled why you resist understanding the mechanism that allows the phase shift to change with coil design.

Please stay on one thing at a time. I have a life besides newsgroups.

Actually that statement proves YOUR theory wrong Cecil, not mine.

I'm saying that in an antenna of fixed length with a fixed coil location on a given frequency, I can change ONLY the coil design, still maintain resonance, and have phase delay of current change significantly.

YOU are the one who appears to be saying all coils and stubs are equal within a small range.

The theory I believe to be correct is the capacitance from the inductor to the rest of the world compared to termination impedance determines phase shift in current and current taper. What is it you think determines current phase shift at each end and current taper?

Explain the logic behind your idea in a way that makes the toroid work, or a compact equal form factor inductor have very low phase shift compared to an entire helice.

My example works in every case. Your's fails, and you cannot just toss out the obvious disagreement and expect people to take you seriously.

These on something like 4 foot or longer extension poles would help
you for a cheap solution to the lower bands. Adding a top hat to the
stinger (yeah, impossible) would go further.

> (I don't have the 102 whip yet.)

Get one, at hamfests they are cheaper than toilet paper.

>I know others who have used the 102 steel
>whip/auto-tuner combination that I have talked to never complained
>that they only received s-2 signals with the system.

They would never notice on receive. The tuner made the difference.

>Therefore, my
>theory is that the winding of the coil on the fiberglass poles is
>adversely affecting the radiation on out-of-band operation. I am
>hoping that the steel whip, with or without the extension, will

A coil loading it halfway up would go further (AKA Bugcatcher).

>I realize it is a compromise but the loss of an s-unit or two in
>exchange for all band coverage for my mobile without having to switch
>antennas or get out of the car and change taps is an acceptable
>trade-off.

Then using a cheap tuner (with a loaded antenna), by all means, is
part of the solution.

>My question is whether or not the tuner itself can hold up to
>the task without being damaged.

As an all band solution, you do stand the risk of one of them being a fire-breather. Just which is hardly predictable with any accuracy given the vast number of variables. There is certainly a strong correlation with longer wavelengths and short antennas. So, you might design two systems - cheaply, of course.

>>Mobile quarterwave dipole?
>base. The suggestion I was given was not to use the antenna tuner on
>a 20 meter dipole to tune a 40 meter frequency. This would be a 1/4
>wave dipole on 40 meters. I don't know what the impedance of such an

>reasonable match.

Again, you should never believe everything you hear.

A quarter wave dipole should be a snap to tune. On the other hand, using an 80M antenna on 40M could be a bear. Also, a quarterwave dipole is only vaguely related to a quarterwave vertical - um, let's just say that relationship is too strained to be compared.

>We never discussed the use of the tuner in the mobile.

That was the first thing you said, it would be quite close to the proposed mount. Anyway, I have always considered it part of your cheap solution and it has a place there.

>I should have clarified that this statement. The internal inductor of
>the tuner makes up the missing length of the antenna and heats up
>which can cause damage to the antenna tuner's inductor. This is how
>it was presented to me, or how I understood it. Again, the discussion
>was using the tuner to tune short dipoles to transmit on lower
>frequencies.

This is another instance of not believing everything - but it at least this time it offers a nugget of truth. This is the spin of the wheel of chance I mentioned above. Don't fret so much and simply try it in the driveway. Open the tuner, fire up the rig and tune for lowest SWR. Let go of the key and touch components to see how hot it's gotten. You don't need infra-red analysis and toolkit of thermocouple probes to obtain a good understanding of the situation. Repeat on all bands.

The J-pole crowd seems to tout fantastic claims about this antenna and I
have never been impressed. Many people have tested the J-pole against
other easy to make antennas and the end fed half wave J-pole usually
does not stand up to even iti¿½s brother, the center fed half wave dipole.
I assume the decrease in performance is due to mistakes in assembling
and tuning the matching section. Here is a link to a group that tested
some J-poles against other antennas in the CA desert and the J-pole lost
to even simple 1/4 wave ground plane types.
www.geocities.com/SiliconValley/2775/anttest.html
My point is, why not make a simple ground plane for the attic that may
not get bothered by surroundings as much as the J-pole.
Bob

1670. Re: question about caps in tuning loops ..

Newsgroup: rec.radio.amateur.antenna
Date: 2006-04-29 17:10:35 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <wLudnQ_m6sqkOc7ZRVnysQ@bt.com>
Source record: 60366

There are other magloop programs beside mine.

Most of the others calculate the size of the tuning capacitor in pF to be that which resonates the calculated loop inductance in micro-henrys.

This is incorrect.

It may be OK for very small loops. But, taking the extreme example. when the loop circumference approaches 1/2-wavelength at the working frequency, obviously no more capacitance is needed regardless of the value of the loop inductance.

But if there is no capacitor then the loop cannot be tuned precisely to resonance! A variable capacitor, with its minimum stray capacitance, is always needed. The inductance being somwhat less than the theoretical value.

It is popularly assumed that the diameter of the small coupling loop must be 1/5th of the diameter of the main loop. Actually this is a rule of thumb and, for an accurate impedance match, the diameter changes somewhat with frequency and the conductor diameter of the main loop.

But 1/5th diameter applies only when the impedance to be matched is a 50-ohm coax. Other feedpoint impedances need a different diameter. The diameter of a 75-ohm coupling loop should be about 1/4 of the diameter of the main loop.

It is common practice to screen the coupling loop by making it from coax cable. This is a waste of time and materials. No useful purpose is served either on receive or transmit.

The coupling loop can be a self-supporting circle of wire of no greater thickness than the inner conductor of the coax cable which serves it. It can be a square or other loop of the same area but a circle is neater.

It is best to make no direct connexion between the main and coupling loops. Isolate the main loop from the feedline and everthing else. Although this may be difficult to do when there are control wires for a motor-driven variable tuning capacitor. Chokes can be used in control wires or bundles of wires.

Just a few hints and tips which come to mind.

Reg.

Roy, W7EL wrote:
"What good are all the books if the information can`t be used to solve a simple problem?"

Many problems fit examples in the books. Some don`t. Implications in my case are sometimes slow to sink in. An example is what Kraus writes on page 227 of the 3rd edition of "antennas":
"Thus, a helix combines the geometric forms of a straight line, a circle, and a cylinder."

Cecil says that RF on a helix may take a short-cut. He may be right. Why would not a wave deviate from the round and round path on a coil and sweep at least in part directly along the cylindrical length? It may be a case for experimentation with a variety of lengths, pitches, and circumferences.

Best regards, Richard Harrison, KB5WZI

I would follow the advice of TCLAY a couple of posts back. I would add
that there should also be a low impedance ground at the shack entrance
where the lightning arrestor is placed. At that same point the rest of
the radio equipment should be grounded. One common ground point for
all. The tower ground should also be run over to that common ground
point.
The AC power that supplies your equipment should have protection
devices that connect to the common single point ground also.

All grounds in the system should be tied together.

The idea of the single point ground is to have all equipment go up in
voltage together if there is a lightning strike and fall together.
This eliminates voltage differences between parts of equipment that
causes damage.

The coax shield should be grounded to the tower at the top and the
bottom of the tower. The tower should have a substantial ground system
of several ground rods and radials.

Look at the Polyphaser site again. They show how a single point ground
system should be installed.

If the language in the Corum paper bothers you, check the math.

The Corum paper gives a mathematical solution of Maxwell's equations for a helix that allows you to answer the questions that have been ongoing in this thread.

I'm not going to claim that I worked through the solution myself. I did read it and try to understand the process. It looks just like what I've done over and over again in electromagnetic theory courses. You write down the wave equation, the boundary conditions, and you solve.

The geometry of the problem leads to lots of bessel functions and the necessity to numerically solve the resulting equations to find the solutions in the middle ground between a lumped circuit coil and a TWT helix.

I feel like this is typical of physical problems that have a limiting case at either end. If you go to infinite propagation speed, or a coil that is very very short compared to a wavelength, you get a lumped circuit.

If you go to a very long helix with respect to a wavelength, the wave on the helix goes round and round the turns.

In the middle, the Corum paper describes the situation in mathematical detail.

Both crackpots and respectable scientists can use complicated terms. The former use them to obscure unverifiable claims, the latter use them to try to put a concise name on something that has a complicated mathematical description.

Throw all the words out of the Corum paper, if you like. Let's look only at the solution. Is there anything wrong with the mathematical solution to the wave equation on the helix presented there? Is the solution in fact applicable to a GIVEN ham antenna loading coil? Can we use it to predict the difference in current at either end of a loading coil for a given ham antenna loading coil?

I was going to write "typical" ham antenna loading coil, but I realized that's a trap. You can't take the solution in the Corum paper, reduce it to a rule of thumb for the "typical" ham loading coil, and then use that rule of thumb to make quantitative predictions about a particular coil in a particular configuration!

Does the solution applicable to all helix sizes and pitches (the transcendental equation, equation 28 for the constant tau) and the

equation for the velocity of propagation along the axis of the coil (phase velocity = omega/beta) give the correct delay or not?

I think equation 28 can be solved in Matlab or Mathematica or something else. I haven't quite figured out if Figure 1 uses approximations or if it is numerical solutions of equation 28. If it's the latter, you can just use the figure.

What's the mechanism which gives this half wave antenna 2.4 dB gain over a half wave dipole?

Modeling shows the gain to be the same as a dipole, if you can manage to keep the current on the outside of the feedline to a small value. If you can't, the gain in the horizontal direction typically becomes less than a dipole.

w8ji@akorn.net wrote:

I'm going to ask a couple of technical question at the beginning
rather than getting them trimmed and ignored in the body:

1. You seem ready to admit that there is 10 degrees of delay
through a 10 degree long stinger. Yet, if you measured that
delay using standing wave current phase, you would measure
a zero phase shift through the stinger. Why aren't you arguing
that there is no phase shift in the stinger?

2. There is no appreciable standing wave current phase shift from
feedpoint to the tip of the stinger in a 75m mobile bugcatcher
antenna. To be consistent, don't you have to argue that the
75m mobile bugcatcher antenna is zero degrees long?

> Cecil Moore wrote:
> So you are saying the loading coil is "7's of feet long". Is that
> correct?

Compared to a straight wire at 4 MHz, yes, that's what I am
saying. A 75m bugcatcher coil uses about 42 feet of wire.
The delay through that coil is *roughly* equal to about half
that number of feet of straight wire. The reason it is not
equal to 42 feet of straight wire is the flux coupling between
the coils.

>>Your assertion that nearly 100% of the coils link
>>nearly 100% of the total flux is unrealistic.
>
> I never said that.

But it would necessarily have to be true for the velocity factor
of the coil to be anywhere near 1.0 and you did say that.

> What's your point in making that switch? We were talking about loading
> coils, now you are switching to stubs. Why?

THE EFFECT EXISTS WHETHER THE COIL EXISTS OR NOT. Which
indicates it is the nature of standing wave current, not coils,
that you do not understand. The standing wave current phase
is unchanging whether a coil exists or not. ONE CANNOT EVEN
USE STANDING WAVE CURRENT PHASE TO MEASURE THE PHASE SHIFT
THROUGH A WIRE, much less through a coil.

Given that standing wave current phase cannot be used to
measure the delay through a wire, coil, or anything else,

it follows that nobody has provided any valid measurements
for the delay through a coil.

>>A very similar thing happens with a 75m mobile antenna.
>>The base loading coil provides tens of degrees of phase
>>shift.
>
> How do you know that?

The stub involves two different Z0's. The 75m mobile antenna
involves two different Z0's, one for the coil, the other for
the stinger. It's the same principles using the same equations.
The phase shift at the impedance discontinuity depends upon the
ratio of those two Z0's. The higher the ratio, the greater the
phase shift. The ratio of 450 to 50 is obviously 9:1.

A rough estimate of the Z0 of the coil is around 2400 ohms and
a rough estimate of the Z0 of the stinger is around 400 ohms.
That makes the Z0 ratios roughly 6:1.

> I'm happy to see you no longer agree with the misplaced notion the
> coil replaces missing electrical degrees, but puzzled why you resist
> understanding the mechanism that allows the phase shift to change with
> coil design.

Speaking of what we both believed two years ago:
I'm happy to see you no longer agree with the misplaced notion that
the coil has equal current magnitudes and phases at each end, but
puzzled why you resist understanding the low velocity factor
associated with helical loading coils. The velocity factor of 75m
bugcatcher loading coils is typically less than 0.1

From the Dr. Corum paper, we have an equation for velocity factor
for coils passing a litmus test. A 75m bugcatcher coil passes that
litmus test with flying colors. The resulting VF is in the ballpark
of 0.04 which is in the ballpark of Reg's VF calculations which is
in the ballpark of Richard Harrison's calculations. Your VF of 1.0
along the length of the coil is the one that is completely out of
the ballpark.

Take your 100uH coil and measure its self-resonant frequency
directly over a large metal ground plane. Keeping everything,
including frequency, the same, cut the coil in half. Add a
stinger to the bottom half of the coil to bring the system back
into resonance at the fixed frequency. We know the delay through
the coil is roughly 45 degrees. We know the stinger is roughly
10 degrees. The impedance discontinuity at the coil to stinger
junction is causing roughly 35 degrees of phase shift. That
tells us that the Z0 ratio of the coil to stinger is about 6:1.

I have been through the above exercise using EZNEC.

So can I - so what? It's the same thing as changing the Z0
of one of the pieces of feedline in my two-Z0 stub example.
No coil is required, indicating once again that your misconception
involves standing waves, not coils.

IMO, you are never going to understand this topic until you
take time out to understand standing waves.

> What is it you think
> determines current phase shift at each end and current taper?

I explained that at the start of the argument two years ago
and it has been posted on my web page ever since then.

http://www.qsl.net/w5dxp/current.htm

Scroll down to:
"Why the Net Current is not Constant Through a Loading Coil"

> My example works in every case.

No it doesn't. Your own current measurements prove that the
current is *NOT* equal at both ends of a coil (and your
phase measurements were invalid). Only one special case toroid
showed the currents at the ends of the coil to be equal. All
the other cases proved that the currents are *NOT* equal.

As Gene Fuller said, the standing wave current phase information
is contained in the magnitude. With a current of 2.0 amps at one
end of the coil and a current of 1.414 amps at the other end of
the coil, it exactly matches the example on my web page. One of
your measurements was very close to 1 amp at one end and 0.7 amps
at the other end. It fits perfectly.

Since Fig. 1 occurs after equation (32), I assumed it was for
equation (32). The three variables in equation (32) are coil
pitch, coil diameter, and wavelength. Those are essentially
the same variables plotted in Fig. 1 with the diameter per
wavelength ratio and the turns per wavelength ratio.

Dr. Corum says that for coils passing the litmus equation
test, the error is less than 10% which is perfectly acceptable
for this discussion where W8JI's VF seems to be off by about
5000%. :-)

Cecil,

Earlier we both agreed the current we measure with a magnetic probe, which is the most common and widely accepted measurement device, is the actual current that causes radiation, heating, and the magnetic induction field. It is the current that heats the element and moves a thermocouple meter, it is the current that cause I^2R heating, and the current that moves past one point in the system if we stopped and counted charges, or if we calculated current based on drift velocity of charge carriers.

So what current is it you are measuring? Charges cannot flow two directions at the same time at the same point in a system. There cannot be drift velocity in two dorections at the same time.

Are you talking about a pulse of current and the return echo?

It is however long it is. If it is 7 feet long it is about ten electrical degrees long on 75 meters, because every foot is about .7 degrees.

> Speaking of what we both believed two years ago:

I never said 1.0, as a matter of fact the coil I measured had a vF
(when compared to physical length) of about .5

I measured delay through an approximately 100uH coil at:

http://www.w8ji.com/inductor_current_time_delay.htm

You can see the big change at self-resonance near 16 MHz. 3.8 MHz is
not near 16MHz, so the behavior is quite different at the two
frequencies.

> Take your 100uH coil and measure its self-resonant frequency
> directly over a large metal ground plane. Keeping everything,
> including frequency, the same, cut the coil in half.

Sorry, I won't cut the last few pieces of miniductor I have like that
in half.

So what current are you measuring?

Now Cecil, get serious.

We all know a stub has distributed capacitance and distributed
inductance. We all know an inductor has the same thing. We can solve
the problem equally well using a network of distributed components as
many others have shown.

> IMO, you are never going to understand this topic until you
> take time out to understand standing waves.

Well, I could say the same to you about coils and capacitors. :-)

> charge carriers.

It is the current that has the equation: Itot = Io*cos(kx)*cos(wt)
Until you take time out to understand the implications of that
equation, you will *never* understand what I am talking about. That
current cannot be used to measure delay. Yet, that is exactly what
you and W7EL did and, in your ignorance, reported as valid measurements
of delay through a coil. If you had a clue to what you are saying, you
would feel ignorant in the extreme.

> So what current is it you are measuring? Charges cannot flow two
> directions at the same time at the same point in a system. There cannot
> be drift velocity in two dorections at the same time.

Just as two water waves can flow in opposite directions using the
same water molecules, two EM waves can flow in opposite directions
using the same electrons.

> Are you talking about a pulse of current and the return echo?

You know that I am talking about the distributed network model,
a superset of the lumped circuit model. Instead of rehashing it
here, please refer to my magazine article at:

http://www.qsl.net/w5dxp/energy.htm

and tell me what it is about that article that you don't understand.

>>2. There is no appreciable standing wave current phase shift from
>>feedpoint to the tip of the stinger in a 75m mobile bugcatcher
>>antenna. To be consistent, don't you have to argue that the
>>75m mobile bugcatcher antenna is zero degrees long?

> It is however long it is.

Exactly the same argument holds for a coil. Think about it. You
cannot deny the validity of standing wave current phase measurements
through a stinger and then turn around and deny that same argument
when it applies to a coil. If W7EL's phase measurements were invalid

for a stinger, then they were equally invalid for a coil.

> I never said 1.0, as a matter of fact the coil I measured had a vF
> (when compared to physical length) of about .5

Sorry, that's still about 1000% too high, still completely out
of the ballpark. What I suspect is that you measured zero delay
through the coil and reported 3 nS because you knew zero was
obviously wrong.

1691. Mobile Antenna Question..

Newsgroup: rec.radio.amateur.antenna
Date: 2006-04-29 21:59:19 UTC
From: Brian Murrey <brian@iquest.net>
Message-ID: <XkR4g.10940$sq5.5363@newsread2.news.atl.earthlink.net>
Source record: 60233

I have a 2004 Ford Tarus SES and I was thinking about putting a mobie HF antenna on it so I can play radio while driving from city to city doing my job.

I have never had a mobile HF rig so I have some questions.

First...is there a website, newsgroup, or some other resource that might have some HF antenna mounting info about my particular car?

I'm thinking about using a hamstick or a Workman Mobile from Hamstop on eBay. I guess the big gnarley triple mag mount would work, but I was also thinking about a license plate mounting kit....any suggestions?

How tall are these types of antennas for 40m, and 20m? My rig is a KX1 and it has 20, 30, and 40 meter capability.

Thanks

Thanks, After reading all this, I will be going to get the antenna. I
have a mount on side of the van. i will re-wire it so it goes to an
SO-239 connector so I can mount the tuner next to the antenna for the
test. if all is well, I will get a hole kit and set it up on the roof.

I like the bug-catcher idea, but I don't have the parts :(.

Thanks, again,
Buck

Brian,

Also check out the Outbacker mobile antenna, I use one of these on my Toyota Landcruiser, and works a dream.
Whatever antenna you decide to get make sure that it is in free space as much as you can, this helps cut down car reflection, which is cases by metal interaction.

I made a robust mount on the spare-wheel frame that hangs off the back of the truck, and this made the job easier. As for mag-mounts, take into full account the speed you may do, and the wind resistance the new antenna will produce. Have heard of operators using a mag-mount for even a smaller antenna, only to see in the mirror, it hanging or laying over the back.

Most mobile antennas are about 1.4mtrs up, my outbacker is approx 1.6mtrs from the base to tip, and this is another 1.2mtrs off the ground.

I can send you a photo if you wish, and helps explain my setup?

All the best, willing to help if you have any further questions.

Kevin, ZL1KFM.

Hi All,

I am in the need of a NZ made Huttons HF antenna mobile base, preferably the tilt-over type.
My last one was lost when my car was stolen, and the mount still attached.

If anyone has one that I might get/purchase, could you please contact me directly.

Regards

Kevin, ZL1KFM

It appears you're comparing a half wave horizontal dipole with a (half wave) J pole. Ground does have a major impact on the performance of the antennas, but the reflection results in loss of a lot of signal power if the wave is at a low angle and vertically polarized. Horizontally polarized waves, in contrast, reflect with very little loss at low angles. I haven't tried modeling it, but would guess that in a typical line-of-sight path where there can be one ground reflection in addition to the direct path, the signal would go through fades and reinforcements as you varied the antenna height. Because of the lower loss of horizontally polarized reflections, the fades would be deeper and the reinforcements stronger with horizontal polarization. On the average, the horizontal would be better (that is, the average signal for all heights would be stronger) because no significant loss is incurred in the reflection. But getting a decent signal would be much more of a gamble.

Those looking at modeling results from EZNEC or similar programs should realize that the far field analysis isn't a good simulation of this situation. Probably the best way to model it would be to model two antennas, one at each location, over ground. Put a source in one antenna (the transmitting antenna) and a conjugately matched load at the feedpoint of the other (the receiving antenna). Then look at the power delivered to the load for various receiving antennas. There's a practical limit to how far apart the antennas can be before numerical limitations are reached, but with double precision calculations they can be quite a distance apart.

The conventional J pole with half wavelength radiator has the same gain as a vertical half wave dipole, again assuming you can keep the current on the outside of the feedline to a low value for both antennas.

>
> However for free space groundplane compared to free space verticle
> halfwave there is gain. Better radiation angle as well.

A quarter wavelength vertical ground plane antenna has the same gain and pattern as a half wavelength vertical dipole, and the same as a J pole (if you can keep the current on the outside of the J pole feedline to a reasonably small value). This is true whether in free space or over ground, and it can be demonstrated by theory, measurement, and modeling.

I have been using a quad-magnet mount with an Antenna Speciallists
antenna (resembles the ham stick) very successfully. The antenna has
been mounted on the roof where I used 75, 40 and 20 meters. However,
being less careful at the time, I lost the 75 meter antenna when I hit
a low bridge at 35 MPH. (something to think about.)

The antennas worked very well, but I got tired of changing them. I
added a mount from under the bumper of my car and was able to use 20
meters there, but the low bands didn't drop SWR below 2:1 so I only
used them on the roof. I have made numerous DX and other contacts
from the roof mounted antennas including an italian station on 40
meters. Once I got two antennas working, 20 on the bumper and 40 on
the roof, I was happy for a while. Now I want more than two bands and
I would like to cover a wider bandwidth, so I have another thread
discussing my latest attempt at a mobile antenna idea.

Good luck, and let us know.

You don't have any WIRE? This is preposterous.

You split the vertical rise with an insulator and wind WIRE to fill the gap. End of story. Your job is to make it mechanically sound at 70MPH and thumb your nose at what may be called Q here.

You want a bigger coil? Have dreams of that Q that marks status here?

Wrap a coffee can with several many wraps of paper so it clears all seams and beads. Wrap turns of wire around the can/paper. Add epoxy in nice neat lines along six lengths around the circumference (use modeling or florist clay to build dams). Wait a couple of days for it to cure. Take out the can and paper. Clean off the clay. Paint it red, white, and blue!

What can 40 or 50 feet of wire, clay, three colors of paint, and an ounce of epoxy cost? $5?

********** REPLY SEPARATOR **********

Fords of any kind are notorious for noise, but if you are determined
to go through with it:

1. A triple mag mount will work fine with HamStick antennas. I use an
IronHorse one and I guarantee that will not come off in the wind. I
can't hardly get it off with a pry bar.
2. Hamsticks are excellent on 20-10 meters and pretty good on 40.
3. Not so good on 80.
4. I don't know what an "SES" is, but if it's shaped like a regular
car (not an SUV) put the triple mag mount on the trunk. No need to put
it on the roof unless you like people staring at you.
5. Run a separate ground wire from the base of the mag mount to the
chassis of the car. Don't rely on the capacitance of the mag mount,
especially on the lower freqs. On ten meters and possibly 15 you might
get away with it, but on 20 and lower freqs your SWR will probably be
high. Use some forethought and make the ground wire as short as
possible, no more than about six or maybe eight inches.
6. Next time get a Chrysler product. :-)

Also, there is a mobileham forum on www.eham.net which may be a source
of more info oriented specifically toward mobiling.

Have fun!

Consider your normal mobile antenna with a large loading coil. Now,
in your mind's eye, replace the coil with a cylinder. Now, compute the
cutoff frequency for that cylinder for either a TE or TM mode and see
how close you can get to 3.75 Mhz. Of course, if your waves are slow
enough, you should be able to cram something in there, but you have to
show experimentally both that you can do it, and how you can do it.

Thanks for all the info guys. I think I am going with a 20m and a 40m Hamstick type of antenna. I will most likely be mounting it to the Taurus (which is a car and not a SUV) with one of those license plate mounting kits. I am making the mounting kit in the metal shop next week. It will be stainless steel and about twice as thick as the one Lakeview sells. I can get a few very good grounds with the license plate mount.

I will then run some 10 ga stranded wires to the battery and fuse both sides near the battery. I will make a connector cable for my KX1 so it mates up OK. The KX1 is only 4w out so I could probably run it off the cigarette lighter...which I might do anyway. I think the cig lighter is rated at 10A so should be over kill.

I am also making a mount for my 2004 Durango so I can move the antenna and rig between vehicles. I have ordered a few of the quick disconnect joints for the mount. I will probably use RG8X for the antenna feed line. The KX1 has a built in antenna tuner.

1707. A little more on missing degrees

Newsgroup: rec.radio.amateur.antenna
Date: 2006-04-30 03:24:18 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <mrKdnUgqFMsZs8nZRVnyjg@bt.com>
Source record: 60249

I havn't much idea on what the present argument is all about. And I
have no wish to take sides.

But -

If Line-1 has impedance Zo1 and is a fractional wavelength L1 long,

and Line-2 has impedance Zo2 and is a fractional wavelength L2 long,

then when both lines are connected together and are brought into
so-called 1/4-wave resonance by pruning the length of one of the
lines, it is IMPOSSIBLE for L1 + L2 to equal 1/4-wavelength or 90
degrees.

There are ALWAYS some degrees "missing" - depending on the ratio
Zo1/Zo2.

Except only when Zo1 = Zo2 will L1 + L2 total 90 degrees.

Can be proved mathematically without invoking standing or reflected
waves. You just have to believe in mathematics.

Line-1, of course, is a loading coil and Line-2 is a whip.

I hope this settles an argument.

For a demonstration download program TWOLINES from website below.

Is there more to the two-piece than just two pieces? Is it a loaded
fiberglass whip with a stinger, or two solid pieces of wire making up
one long stinger. If so, the cb whip is longer, if you have a loaded
section, the loaded section is longer.

I believe the SGC whip is continuously loaded with a tapered pitch over a large diameter fiberglass core and also has a straight internal shorter section for higher freqs. No top stinger, just big, thick, ugly black heatshrink coated. I think it resonates around 13 and 22MHz. Look up an SG-303 in Google.

I question that 7-8 year figure. Some Finnish friends put up a "temporary" tower with a tribander at the OH0Z site in the 1990s. They used new polypropylene ski rope. I went out one weekend and there lay the tower and tribander, victims of a guy rope failure. I'd NEVER use the stuff for guying or antenna supports.

> Polyester rope as used on sailing boats is UV resistant (even without
> carbon black) and would last 30+ years ,but it is relatively expensive.

Polyester is excellent material. There is a polyester rope sold under the "Synthetic Textiles" name here in the U.S. which is simply great. It is braided, not twisted. The inner core is white. There is an outer braid which is black. I have some which is fourteen years old. It is still strong and flexible.

> Plastic antenna insulators (sold in the UK) are usually black , so are
> the outdoor balun enclosures and plastic insulators on Yagi antennes.

We're now seeing some white plastic insulators here. I tried some in the sun of Africa. They looked like they were pitted and deteriorating after three years in the sun of Botswana. I either use ceramics or make my own out of 1/2" thick clear plexiglass sheet or 3/4" plexi rod. That yellows but doesn't otherwise seem to deteriorate.

If we have three sections and Z02 > Z01,

---Z01---+---Z02---+---Z01---

the first impedance discontinuity causes a phase
shift in the *opposite* direction from the second
impedance discontinuity. That's why moving a loading
coil from a base-loaded position to a center-loaded
position requires more degrees of coil.

W8JI has been trying to make a big deal out of that
fact but it is just simple physics.

TE, TM, or TEM a small loading coil cannot behave very much like a transmission line.

If you read the Corum paper carefully, you see he clearly states it is an approximation or solution for a coil under the very special condition of being self-resonant.

He is working on Tesla coils, not loading coils. He is working with coils that have essentially no termination and that actuallly behave like a series of L networks with high reactance shunt C and high reactance series L.

Worse yet, we have one person who is trying to use a large diameter helice with wide turn spacing that is large enough to support TEM waves as a comparison to a tiny fraction of a wavelength dieameter and length inductor that has relatively close turn spacing and tight coupling from turn to adjacent turn.

Unless we do something to cause the radial electric field to be very intense and support significant displacement currents, all the standing waves in the world external to the won't make a coil behave like a linear conductor.

Notice also how Cecil misquotes to make a point. The Vf I measured on 80 meters for a large bug-catcher style coil was actually .5 compared to spatial length, not 1.0

On the other hand Cecil has measured virtually nothing, Yuri has measured nothing, and Harrison probably hasn't even owned a bug catcher coil being a technician class license holder.

It's easy to dismiss measurements when you have not done a thing on your own except talk.

That's where you are wrong Cecil.

While the effects of energy and reflection of current and voltage can
be considered as a real actionl, current actually can only flow one
direction at one time at one point in one conductor . There is no other
way.

You are confusing a model that is supposed to aid people in solutions
as the "real" thing happening.

Every single thing that can be done with standing waves can be done
with circuit solutions, and we cannot have charges moving two
directions at the same time at any one point in the system.

The radiation from a short antenna is easily tied directly to
ampere-feet, and the amperes that cause that radiation **is** the
current Roy and I measured. The current Roy and I measured is the
current level causing heat.

Be assured that along the short length of the conductor at any fixed
instant of time in one spot, you cannot possible have two potentials or
charge differences causing charges to move two directions at once.

What you are saying is you have something that cannot actually happen
and even if it could it has no effect and cannot be measured, and that
is what is important to you and makes the rest of the world wrong.

No wonder no one can agree with you!

73 Tom

Sorry Cecil, I cannot get into my network analyzer and make it show a delay on a printout that isn't actually there. I push the button, it prints the data it takes.

In an attempt to justify your odd conclusions, you are now altering my measurements.

At this point any further exchange is useless, because you have now resorted to calling the other person a liar when measured data disagrees with your preconcieved notions.

I'm done with you.

w8ji@akorn.net wrote:
> TE, TM, or TEM a small loading coil cannot behave very much like a
> transmission line.

We are not discussing small coils, Tom. We are discussing big
honking 75m bugcatcher coils. Why do you guys always retreat
from the real world into the area of "small" coils?

> If you read the Corum paper carefully, you see he clearly states it is
> an approximation or solution for a coil under the very special
> condition of being self-resonant.

False. He clearly states that the VF and Z0 were established at
the self-resonant frequency and that those values hold as long
as the coil pitch, coil diameter, and frequency remain unchanged.
That's exactly what I have done using EZNEC models.

> He is working on Tesla coils, not loading coils.

The first words in the title are, "RF Coils, ...". Figure 2
looks just like a 75m bugcatcher system with a top hat. A
75m bugcatcher coil is a helical resonator that brings the
antenna system into resonance.

He has a litmus test for RF coils. If the coil dimensions
pass the litmus test, then his VF and Z0 equations are known
to be valid within 10%. A 75m bugcatcher coil passes that
litmus test by a 100% margin.

A self-resonant coil is 90 degrees long. Dr. Corum says the
lumped circuit model doesn't work until the coil is trimmed
down to 0.167 of that length. Seems you have proven that to
be true.

> Notice also how Cecil misquotes to make a point. The Vf I measured on
> 80 meters for a large bug-catcher style coil was actually .5 compared
> to spatial length, not 1.0

Sorry, my memory was faulty on that one but 0.5 is still 1000%
different from the value predicted by Dr. Corum's VF equation
and flies in the face of known technical facts about coils.

> On the other hand Cecil has measured virtually nothing, Yuri has
> measured nothing, ...

Which is better, Tom. Valid science or invalid measurements? You
still haven't answered my question as to why you don't just
assert that a 1/4WL monopole is zero degrees long since there is

zero degrees of phase shift in the standing wave current phase
from end to end in the antenna. Heck, you can even prove that
a 1/2WL thin-wire dipole is zero degrees long using the same
measurement techniques that you used on a coil.

> ... and Harrison probably hasn't even owned a bug catcher
> coil being a technician class license holder.

Instead of belittling his ham license, how about you compare
your technical degrees to "Harrison's"?

Ok, That makes sense

That gives me an idea. I wonder what stacking my 20 meter base on top
of my 40 meter base would produce. I'll try that today. I did some
testing, see my followup in this thread.

Thanks
Buck

> prints the data it takes.

Yes, and you have previously said that any answer is better than
no answer at all, presumably including answers obtained using
invalid measurement techniques.

If you take your network analyzer and measure the current phase
shift from end to end in a 1/2WL thin-wire dipole, you can prove
that dipole to be almost zero degrees long, just like you did with
the coil.

> In an attempt to justify your odd conclusions, you are now altering my
> measurements.

Please don't blame my faulty memory on any ulterior motive. It was
an honest mistake easily proven to be wrong. (And a VF of 0.5 is
just as unbelievable as a VF of 1.0 for a foot long 8 tpi coil.)

> At this point any further exchange is useless, because you have now
> resorted to calling the other person a liar when measured data
> disagrees with your preconcieved notions.

I apologize for my faulty memory, Tom, and everyone knows that I didn't
call you a liar. I accidentally misquoted you and you corrected me.

Your measured data simply disagrees with known technical facts. Until
you take time to understand the technical implications behind the
standing wave current phase that you used for your measurements,

Itot = Io*cos(kx)*cos(wt)

you will never understand why using such a signal to measure phase
is an invalid thing to do. Hint: the phase of the above standing
wave current doesn't vary with 'x' so it cannot be used to measure
a phase shift between point 'x1' and point 'x2' on a wire or
through a coil.

1726. TT-247 and 102 whip for mobile antenna ? testing

Newsgroup: rec.radio.amateur.antenna
Date: 2006-04-30 12:55:49 UTC
From: Buck <not@this.time>
Message-ID: <b2c9525v2bq3ah5l523rl7qploepudc06d@4ax.com>
Source record: 60268

Yesterday I bought the whip and put it on my existing ball mount on the back left corner of my van. I still have the coax running to it so there is about 20 feet of RG-58 (RadioShack brand) running from the antenna to the tuner.

My preliminary results weren't good. It tunes all ham bands from 6 thru 17 easily. 20 starts getting finicky and the bands below seem to cause arcing.

On the receive side, I am able to receive much better with the CB whip than with either the 40 or 20 meter AS antennas on bands other than what the AS antennas are designed for.

On transmit, things aren't so well. On 75 meters, I was able to hear one person acknowledge that there was a mobile calling. I heard no other response with any other band. Mind you, I was doing this from just about sunset until about 11 PM with a long break for supper and a short shopping trip. This wasn't the ideal time to test the antenna for any band other than 40 and 80.

I heard some activity on 60 but no one responded to my call.

Today, if I don't get called into work, I plan to cut the wire next to the antenna mount and install an SO-239 so I can wire the tuner directly to the antenna or connect the coax to run to the front of the van where I have the radio mounted.

I will test the antenna and try to compare it to the 40 and 20 meter as antennas.

Just for kicks and giggles, I stacked the two antenna bases for 20 and 40 meters and added the steel whip to the top of the combo (that's about 12 feet tall plus the height on the van.) The results weren't good. The steel whip was too heavy and caused the antenna to bow to the ground. I will try them today with and without the stinger to see if that is a better combination than just the one band antenna. hmm, 20 + 40, that's 60 meters, right? lol.

It's 9 am here in Charlotte. I am going to read my email and go experiment some more.

73 for now.

SGC recommends that no transmission line be used between the
tuner and the antenna because of arcing. Consider that to
force just one watt into a CB whip on 4 MHz, EZNEC says it
takes over 1700 volts.

Interesting. Thanks.

I am still testing. I tested with coax and the result is that the
antennas designed for a given frequency work much better on their
frequencies. I am looking for my soldering kit now for the
connectors.

I may try a direct connection to see what happens without coax if I
can.

Everyone wants to use the most unreliable instrument they possess, their brain, to measure natural phenomena. The Corum boys wrote an entertaining paper that makes use of what is evidently an old technique for explaining helical behavior in the microwave range to make a point about self-resonant coils being superior to coil-capacitor combinations for producing long sparks in Tesla coils. Taken literally, the paper misses the magic ingredient of validation by experimentation. There are speculative papers all over the web that do the same thing, but without experimentation and measurement their most useful purpose is to provide ideas for people who are willing to do the grunt work of designing and setting up experiments which show how good the mental approximations are, their limitations, and their usefulness. I don't think the Corum paper is worth much at 3.75 Mhz. Maybe some of the fellows on this newsgroup can design and carry out an experiment that shows me wrong. I'd be delighted to be able to use a loading coil as a low-frequency waveguide. In the meantime, I don't see any use in Cecil quoting from Corum's paper as if it were received wisdom while its conclusions are no more proven than the ideas Cecil is trying to prove.

I don't understand the argument either. Why would anyone care
how many degrees an antenna has; it radiates all the power
whatever its length.

Tom sure hit the nail on the head this time, didn't he, Cecil.
When are you guys going to do your own experiments and
measurements. Yuri at least threatens to do them. You just
use a fast mouth and a few hick rhetorical techniques to get
someone - anyone - to go along with you. A man can justify just
about anything with his mouth, including CFA antennas and their
kin, but providing repeatable experiments and measurements
is something else again... ain't it.

1736. Re: TT-247 and 102 whip for mobile antenna ? test complete

Newsgroup: rec.radio.amateur.antenna
Date: 2006-04-30 16:29:54 UTC
From: Buck <not@this.time>
Message-ID: <lso952p0lcqi7his0lqq85vm49ulv7nra4@4ax.com>
Source record: 60178

I just finished testing my antennas. The result is that the
whip/tuner combination is unacceptable.

I took the coax off the ball mount and ran short wires, about 6 inches
from the center lead of the ball and from the ground screw at the ball
inside the cab of the van and ran them to the appropriate connectors
on the tuner. I then tested 75, 40, and 20 meters.

The test results were that I made no contacts on 75. The only thing I
heard was a very slow and long monolog on 3872 by some man who seemed
more to be broadcasting than talking to another individual. I waited
over ten minutes to see if he would break or identify, but he did
neither. I went to 3.915 and heard two stations go QRT, but received
no response when I called. I didn't have another antenna worth
testing on 75 so that concluded my 75 meter test. Results: NO JOY!

I went to 40 meters where I heard some conversations. It tuned up
more easily than on 75, but no one answered my calls. I swapped to
the 40 meter AS antenna and the stations I heard went from no signal
on the scale to over s-9. That was enough to resolve that test.
Results: NO JOY!

I went to 20 meters where I had more success. I talked to Jim on the
county hunter's net with the whip antenna. He was the only station I
was hearing at the time. I swapped to the 20 meter AS antenna and his
signal strength went from s-2 to s-9. Also, I was able to hear the
mobile that was running. Results: NO JOY!

I hooked the coax back up, setup the 20 meter AS antenna and tuned it
from the front of the car. I will not be drilling a hole and
rearranging all the roof antennas for the whip. I will rather focus
my attention on getting the rest of the parts of my screwdriver
together after I get paid next week and see if I can install it.

Thanks for all the comments.

If nothing else, all this testing did reveal a bad ground connection
from the coax to the cab of the van. It is now fixed.

73 for now.

Tom is correct here, a smaller wire has more inductance than a larger wire. The resason is that the current paths on a large conductor become far enough away from other current paths on the surface of the same conductor, that their magnetic flux lines begin to not totaly include each other. Therefore the parrellel current paths do not have total mutual inductance. A big wire begins to act like several parrellel wires. Inductors in parrellel produce a smaller inductance. The bigger the conducter the greater the effect.

Adding an inductor in the middle of an antenna wire lowers the resonant frequency. To keep the same resonant frequency when inductance is added, you need to shorten the wire. The inductance added by making a wire smaller is totaly distributed along its length which changes slightly the results compared to the example of adding a lumped inductance in the middle of a wire antenna but the priciple is the same.

Bottom line, smaller wire means more inductance and a shorter lenght for the same resonant frequency. Bigger wire means less inductance and a longer length for the same resonant frequency.

Speaking of antennas by the way, have a look at my 5 element log cell 20 meter beam. I have a photo of it on QRZ. http://www.qrz.com/ac7pn

Tom Donaly wrote:
> When are you guys going to do your own experiments and
> measurements.

I've already done them and reported them here, Tom. Here's the procedure again.

1. Take a sample coil and measure the 1/4WL self resonant frequency over my GMC pickup ground plane.

2. Keeping everything else the same, cut off half of the above coil.

3. Add enough straight wire as a stinger to bring the antenna system back to resonance at the previous self-resonant frequency.

4. The delay through half the coil at the self resonant frequency of the whole coil, is known to be 45 degrees. The stinger is 11 degrees long. The impedance discontinuity between the coil and the stinger provides the other 34 degrees of phase shift.

Both sides of the argument assumed only two phase shifts were involved. Both sides were wrong. The third phase shift is obvious once you know it exists and is perfectly visible on a Smith Chart. When the impedance at Z01 is 1.0 on the Smith Chart and transforms to 9.0 on the Smith Chart for Z02, that's obviously a large phase shift.

Two years ago, both sides agreed that the stinger was about 11 degrees of the antenna.

1. Side 1 said that the base loading coil acted as a purely lumped inductance providing 79 degrees of phase shift essentially at a point.

2. Side 2 said that the base loading coil provided a 79 degree delay like the delay in a transmission line, which was the source of the 79 degree phase shift.

At that time, both sides were unaware of the phase shift occuring at the impedance discontinuity point.

Now we know that both sides were partially right and partially wrong. As side 1 said, there is an abrupt phase shift at a point. As side 2 said, there is a delay through the coil. The truth seems to be just

about in the middle of the two previous arguments
which should make both sides happy.

There are tens of degrees of delay through the coil.

There are tens of degrees of abrupt phase shift at
the coil to stinger impedance discontinuity.

Both sides were equally right and equally wrong. Who
won? Both sides. Who lost? Both sides. This is the
invariable result when both sides are forced off the
rails by reality.

Why does EZNEC report that increasing the wire diameter results
in lowering the resonant frequency?

1745. Insulation diameter vs Impedance OR how to get 20dBi out of a short Dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2006-04-30 18:23:18 UTC
From: Richard Clark <kb7qhc@comcast.net>
Message-ID: <jes952lr3vn6jitg2bs80gn2t9bm614lgl@4ax.com>
Source record: 60187

Hi All,

This is a variation on themes being played out. As the title suggests, you too can force your modeler to give you phenomenal results in just 5 minutes! Think of it, 20 dBi from a short Dipole - but first the story:

While I was pondering the coil current flow tricks, I mused over the thought of instead loading a short antenna with the inverse of inductance, capacitance. Instead of using suspect lumped loads, I instead chose to load the wire with insulation. And not just any insulation.

Insulation found on typical wire comes in a vary small range of values. They exhibit dielectric constants from 2 to 4, and rarely that high. If I were to take a load of it, say in the form factor of a Texas Bugcatcher coil - what would happen?

Not much it seems. However, I am not one to let that slow me down and I considered a list of elements and materials to examine them for the highest DCs available. I was thinking of waxes primarily. The thought ran that I would turn a small HF antenna into a candle and see if that would slow the Vf.

Waxes do offer higher DCs, but not markedly so. I started to think salts next, considering that the common round salt box was about the same size as a large coil. Salts have a high DC (up to the teens), but even there, not much effect.

Then I turned to what is commonly available, and exhibits a very high DC - water (dielectric constant of 80). I started with a meter high tube of 4 inches diameter (been thinking a lot about plumbing this week when contractors built a French drain in the basement) and plunked a short (5M) vertical antenna into it.

THIS made a difference. (OK, so did others, but not like THIS).

What the hell, I started to make the diameter bigger to see where the limits of failure were. Turned out to be around 12 inches thick water jacket. This was for a monopole in a truck bed I though (fair amount of weight and sloshing in this linear load). However, it had the intended consequence of providing 5.6dBi gain.

Now, this gain has to be taken in the perspective of the unjacketed radiator that exhibits -4.85dBi gain. More than 10dB gain by adding this water jacket! Hosanna! Of course, if I trimmed this thickness to goose up the gain, THEN the modeler failed with reports of negative

resistance (due to possible problems that could not possibly exist).

Well, time to reduce complexity and do the same thing with a short dipole in space (10M long excited at 3.8MHz). This antenna is constructed with 10 wires so that only the first wires closest to the feed are insulated. I increased the size of the water jacket and noted results for drive point impedance, average gain, and best gain. The binomial progression is edited from a longer list. The results are as follows:

Thickness Zfeed AvGain Gain
mm Ohms dB dB
0 4.1 - J 1646 -0.02 1.77
10 3.726 - J 1437 0.039 2.17
20 3.498 - J 1305 0.66 2.45
40 3.2 - J 1133 1.05 2.83
80 2.848 - J 930 1.55 3.34
160 2.46 - J 705.8 2.19 3.98
320 2.051 - J 469.5 2.98 4.77
600 1.67 - J 249.5 3.87 5.66
1211.67 1.238 - J 0.0013 5.17 6.96
2200 0.8685 + J 213.2 6.71 8.5
4000 0.4971 + J 427.7 9.13 10.92
8000 0.0656 + J 676.9 17.93 19.71

As you can see, a water jacket 16 meters wide around the first meter(s) of the dipole offer considerable gain and nothing suggesting that further enlargement was going to upset this trend. I wasn't going to push it anyway because it looked exceedingly suspicious.

As suspicious as it may appear, it shows a rather smooth progression. It was pleasing to note how the load reactance shifted from capacitive to inductive. I posted a note to Roy who confirmed the intent for the insulation entry was to limit it to common coating dimensions. However, there is nothing in the data to suggest a logic breakdown in my progressions.

On the other hand, when I pushed this further by reducing the wire size (10 wires per element instead of 5, while keeping the same total length), I noticed the effect was more remarkable:

Thickness Zfeed AvGain Gain
mm Ohms dB dB
1000 0.2847 + J 139.9 10.98 12.76

A 1 meter water jacket on a shorter wire induced more gain than the former 4 meter water jacket from the series of results above.

To me, this suggested a boundary violation more so than a thickness failure mechanism. There are cautions or prohibitions in connecting different size wires, it seems that extends to insulations' diameter mismates even when the wires' diameters (25.4mm) are identical throughout.

So, the object lesson seems to be
Do not try this at home,
or
in the back yard;
or
Do not fill your truck bed with water flooding your HF antenna

Can anyone tell me about this RoomCap Antenna?

The best I can find on the antenna is a picture of what looks like a
piece of PVC with a capacity hat on it.

I keep getting advertisements on the email reflectors and when I check
the website, it asks for me to email for more information. I have
done so several times and never received a response.

What can you all tell me about this antenna?

Thanks,
Buck

I lived near a lake that has about a 3 mile circumference, what kind
of gain could I expect if I sank my antenna in the lake and operated
marine mobile from a wooden boat?

Cecil has the above diagram. Tell me if I am wrong, but would not the Icom automatically stop tuning the antenna when the swr drops to it's low if it is below 1.5:1?

A 15 ft long horizontal dipole, #14 AWG, on 3.8 MHz,
has a radiation efficiency of 90.17%. The loss due to
heat is 0.45 dB.

Designing an efficient matching network may be difficult.
Even with 100 W delivered to the antenna the 52 kV
at the feedpoint may pose a problem.

Frank

I don't know who Kurt ? is...maybe I would.

If the calculations get out of hand...maybe I wouldn't.

Wouldn't be weird if someone had to reverse engineer a garbage to define
an antenna?

1753. Re: Wire diameter vs Impedance

A wonderfully logical explanation. But there's something wrong with it because the conclusion it reaches is demonstrably wrong.

An antenna made with a larger diameter wire must be made shorter, not longer, than one with a smaller diameter wire to maintain the same resonant frequency.

Tom, W8JI wrote:
"--Harrison probably hasn`t even owned a bug catcher coil being a technician class license holder."

You don`t need to own things to understand them.

I have a technician class radio amateur license renewed after its initial ten-hear term. My First FCC license was a 1st class radiotelephone license passed on my first attempt at the test in the Houston FCC Office in early 1949. Shortly thereafter I got a call from a Houston broadcaster that resulted in employment at a plant housing two AM atations which shared a common antenna system. From there I went to work in medium-wave and shortwave broadcasting stations for a dozen years, got several college degrees including a BSEE.

I took a job with a petrochemical conglomerate which called me in 1960 saying that it intended to "automate" its operations and they thought I might be helpful. In their employment, I installed low-frequency aircraft beacons, 6-GHz microwave, shortwave AM, FM, and SSB. Installed telephones and electric power plants.

The conglomerate found, produced, transported, traded, refined. manufactured and marketed oil and gas and products made from them. That was only a start. The company mined materials from the earth and from the sea bottom. It farmed, manufactured tractors and automobile components and tools. It built nuclear submarines, surface ships, natural gas tankers which consumed their own boil off, and it laid pipe across Canada and the U.S.A. It even consulted for other countries on the best ways to install and operate pipelines. I worked with a handfull of others for the subsidiary that did that for awhile. The company sold insurance because insurance companies have mush of the capital, and for a similar reason it bought and operated banks.. We made PVC and other chemical products. I worked in many of the company`s divisions when they asked for my services. We eventually put the pipeline divison under computer control from from Houston dispatcher`s office. Hundred of remotes were involved between Maine and Mexico.

I`ve wound plenty of coils and tuned many mobile whips with my own hands. We used HF radios from Ecuador to Tierra del Fuego. I`ve worked on HF and VHF radios in the company`s aircraft. When I retired in 1986, I was manager of telecommunications.

Best regards, Richard Harrison, KB5WZI

That's your idea of careful experimentation is it? First start out
with a controversy that doesn't exist, then prove what everyone knows
in the first place. So what part of the experimentation addresses
the "sheath helix" model of their Tesla coil, Cecil?

The only problem with that, Cecil, is that in neither the coil nor the inductor do you have a uniform Z0. Since the capacitance per unit length is a variable, so is Z0 which is dependant on it. You've been sucked into Reg's practice of assuming an average Z0 in order to do calculations, but in your case it won't work because you have to posit two distinct Z0s to have your impedance boundary. In actuality, there's a constant change in Z0 up and down both the stinger and the coil so your idea is a bust. By the way, if you or the Corum boys really want a transmission line resonator for your antenna/Teslacoils you should switch to a helical resonator, the kind ensconced in a can. Of course, the sparks will be disappointing, but the theory will work better.

The gradual change in Z0 really doesn't matter. What matters
is the *abrupt* change in Z0's at the coil to stinger impedance
discontinuity. That's where the abrupt phase shift occurs.

It only matters from a quantitative standpoint and it
matters not one iota from a conceptual, qualitative
standpoint. We already have real world transmission
lines that change Z0 gradually. They obey the laws
of physics.

Hi Richard,
Impressive carreer and background!

That should slap another giant egg on the face of the technical imposter and "guru" parading as "know-it-all" riding on a high horse of plagiarized material.
When he fails technical arguments, he resorts to name calling and insults.
We still have to find out where he got his engineering degree and by what rights he uses "JI Engineering".
Comparing your professional career to his "design" career like Dentron Clipperton L amplifier "capable" of producing barely 600W instead of 1200 on 160 due to joke of a final tank design and his digs at people illustrates the pathetic behavior.

His modus operandi is to defend his wrong "knowledge", ridiculing and trivializing those who know better, then he realizes he was wrong, then he goes quiet for a while, then he twists and "adjusts" his arguments "showing" he said the same things, few months later he surfaces as a guru on the subject, proclaiming the gospel that he fought in the first place. Been there few times with him. He is incapable to engage in decent technical discussions if he thinks different. Will not admit being wrong, but will resort to personal digs when runs out of ammunition.

BTW W9UCW and K8CFU did years of tests and measurements and shared some results pointing to the real behavior of the current in loading coils, but W8JI can make a coil that has the same current at both ends - end of story, because he proclaimed that current is ALWAYS the same and Kirchoff said so, never mind the reality of standing wave current. According to him, the RF chokes should not work either, let's hear some "'splanation".
Oh well, there is bad apple in every RF barrel.

Hi Tom,

For those who don't know, titanium dioxide's dielectric constant runs
about 110.

If I wanted to be truly absurd, I would have done it with Hydrocyanic
Acid (DC of 158), or less aggressively with 35% Hydrogen Peroxide
(121), or back to the acids with Sulfuric Acid (100).

As far as being absurd, yes, this does qualify in spades. However, I
found I could reduce the size of a 40M antenna to nearly half by
surrounding the entire radiator with a water jacket only 40cM thick.
It has a good match, and loses roughly a quarter dB to the full size
antenna. It remains to be seen if this is just another aberration, or
is an actual solution.

Source record: 60220

For those of you who may be unfamiliar with the mathematics of
transmission lines, download program TWOLINES and enter the following
practical values -

Line-1 represents the loading coil.
Line-2 represents the whip to be pruned for 1/4-wave resonance.

Enter Zo1 = 6000 ohms, a practical value.
Enter electrical length L1 = 0.15 wavelengths.
Enter attenuation = 0.1 dB for wire loss in coil.

Enter Zo2 = 400 ohms, a practical value.
Enter electrical length L2 = 0.0077 wavelengths.
Enter attenuation = 0.001 dB

Enter open-circuit load resistance = 100 Megohms and load reactance =
100 Megohms.

To check that the circuit is in 1/4-wave resonance, vary plus or minus
length of Line-2 for zero or minimum input reactance.

The input resistance of the coil or Line-1 is about 16 ohms, a typical
value.

But L1 + L2 = 0.1577 wavelengths = only 57 degrees.

The missing 90 - 57 = 33 degrees are just not needed for resonance.
So why is everybody making such a fuss about it?

Your are right Roy & Cecil. I just confirmed using NEC and looked it up in the ARRL hand book as well. I' happy to not be carrying around that misconception any more. I'm just a little embarased having passed myself off as some kind of expert.

I've spent a lot of time using NEC and have actually built a lot of the antennas I've designed using it, with excellent results. It just goes to show that successfully using CAD doesn't neccessarily impart wisdom.

I'm sure the larger conductor has less inductance but as Yuri Blanarovich pointed out earlier the bigger conductor has more capacitance to free space and that effect must dominate the effect inductance reduction.

>From page 22.2 of the 2005 ARRL Handbook

"CONDUCTOR SIZE"

"The impedance of the antenna also depends on the diameter of the conductor in relation to the wavelength. If the diameter of the conductor is increased, the capacitance per unit length increases and the inductance per unit length decreases. Since the radiation resistance is affected relatively little, the decreased L/C ratio causes the Q of the antenna to decrease so that the resonance curve becomes less sharp with change in frequency. This effect is greater as the diameter is increased, and is a property of some importance at the very high frequencies where the wavelength is small."

Lots of interesting graphs and charts in the ARRL Antenna Handbook as well.

< snip >

A quick look at the numbers doesn't make the j-pole look so all-fired bad. "Losing" by 1 dB or so isn't a serious loss. Ham radio isn't exactly the Kentucky Derby.

I don't know what "fantastic claims" you've heard, but my affinity for the j-pole comes from its simplicity and durability. It's a halfwave vertical that requires no ground plane and can often be matched to 1:1 at the sweet spot. Mounting is a dream -- it even works if you drop the low end into a plumbing vent pipe. (How would I know that? ;-)

I have never built a center-fed halfwave, but we use a bunch of them in the Navy -- call them "stovepipes" because of the way the fiberglass housings look -- and they work very, very well. The elements are large metal cylinders, tending to make them quite broadband. I do not know how they're fed ... balun or what.

Me too. Oh, how much fun we have right after saying, "I wonder what
happens if ... "

Yeah, sometimes it's a burnt finger or a blown fuse, but even then we

==========
A nice summary.

But to be more precise, it is the ratio of conductor diameter over
length which matters.

Inductance and capacitance change very slowly with diameter/length.
The changes are hardly noticeable.

L = 0.2 * Length * (Ln(4 * Length / Dia) -1) microhenrys.

C = 55.55 * Length / (Ln(4 * Length / Dia) -1) picofarads.

Zo = Sqrt(L / C) = 60 * Ln(4 * Length / Dia) -1) ohms.

Antenna Q = 2 * Pi * Freq * L / (Distributed Radiation Resistance).

For a half-wave dipole the distributed radiation resistance is 146
ohms, or twice the feedpoint resistance.

Reg.

Hi Robert,

For a wire, that is not in dispute.

>but as Yuri
>Blanarovich pointed out earlier the bigger conductor has more
>capacitance to free space and that effect must dominate the effect
>inductance reduction.

And yet it does not. Components that are significant in size with relation to wavelength do not exhibit the same qualities. That much is glaringly obvious.

The problem here is one of a Transform acting upon the expected outcome. It is generally cautioned here not to treat an antenna as a transmission line, but this is cautious to the point of ignoring the solution.

Schelkunoff developed a general formula for the dipole by employing a biconical structure. This structure operates in the TEM mode and fits radial expressions for fields naturally described in Maxwell's curl equations which would be tedious to describe here - so we simple cut to the chase.

Schelkunoff reveals, mathematically, that this transmission line analysis presents a finite terminating condition for the current traveling radially (that is, along the wire out towards the end). Hence, the biconical form as transmission line never terminates in an open.

In developing this model towards the thin radiator, the angle of the cones of the biconical structure fall to a very small value. With this, the biconical math also simplifies. This simplification does approach the transmission line condition of an open termination.

The thick radiator falls in between as it is obviously neither thin, nor conical in shape. As a consequence, neither is it a transmission line that has an uniform Zc along its length. The formulas usually used to describe its Zc are an average.

The easy answer comes from this. The two conditions of going from thick to thin involve two different mathematical basis (providing you aren't simply going from kind-of-thin to kind-of-thick). This mathematical basis is transmission line math built on wave mechanics,

not inductors and capacitors. Those are components whose geometries
and size wavelength has condemned to less than useful analogies.

Surely it is your model that is an aberration. Did it include such things as the loss tangent of the dielectric and the effects of the resistivity of the liquid ?

Di-electric loading is a valid concept, but it has to be done sensibly, and modelled even more carefully, taking ALL the effects of the di-electric into account. GIGO.

The same material can be either good or useless, depending on the application.

For example, Delrin has been used very successfully for the mounting pillars of PA tank coils at the 1.5kW level because the dielectric stress happens to be low there... yet I once had a 20W VHF transmitter that melted Delrin in 20 seconds, simply because I was trying to use it in the wrong place.

Likewise, black carbon-loaded plastic can be fine in some antenna applications, but foolish in others. Good locations would generally include long spreaders for open-wire line, because the wide spacing reduces the electric field gradient between the wires. The same applies to centre insulators for multiband doublets, because the connection points are usually several inches apart.

Driven element connections for VHF/UHF yagi antennas are OK because this is always a low-impedance, low-voltage point. The same applies to standoff insulators for parasitic elements. I never heard of black plastic breaking down in these locations - not for electrical reasons - so you can safely concentrate on mechanical strength and UV resistance.

An area where plastics are notably worse than ceramics is surface tracking. This is important for some antenna applications, because a surface track can start along a build-up of atmospheric dirt. If a plastic (or any organic insulator like phenolic) begins to break down along its surface, the losses in the carbonized track become much worse, and the track continues to eat into the base material.

The flaw is that the "wire insulation" feature of EZNEC is valid only for thin coatings, such as those typically found on insulated wire. I suspect it may also be invalid also for extreme values of dielectric constant. I don't at present know exactly at what thickness or dielectric constant the calculation becomes invalid, so results from models with exceptionally thick and/or high dielectric insulation should be viewed with some skepticism.

These limitations aren't spelled out in the EZNEC manual, an oversight on my part for which I apologize. They will be included in the next update to the manual, which will probably be included with the next program update (v. 4.0.27).

> Enter Zo1 = 6000 ohms, a practical value.
> Enter electrical length L1 = 0.15 wavelengths.
> Enter attenuation = 0.1 dB for wire loss in coil.

Ignoring losses and starting at 0-j0, plotting this value
on a Smith Chart normalized to 6000 ohms, the normalized
value is -j1.38

-j1.38 * 6000 = -j8280 ohms

> Enter Zo2 = 400 ohms, a practical value.
> Enter electrical length L2 = 0.0077 wavelengths.
> Enter attenuation = 0.001 dB

Starting at 0-j*infinity and plotting backwards, this value
on a Smith Chart normalized to 400 ohms is -j20.7

-j20.7 * 400 = -j8280 ohms

> But L1 + L2 = 0.1577 wavelengths = only 57 degrees.

The abrupt jump from -j1.38 to -j20.7 provides a 66 degree
phase shift in the angle of the reflection coefficient as
read off the Smith Chart.

> The missing 90 - 57 = 33 degrees are just not needed for resonance.
> So why is everybody making such a fuss about it?

The missing 33 degrees are there, provided by the phase shift
in the reflection coefficient. The angle of the reflection
coefficient in the stinger at the impedance discontinuity is
~6 degrees. The angle of the reflection coefficient in the
coil at the impedance discontinuity is ~72 degrees.

72 - 6 = a 66 degree jump in the angle of the reflection
coefficient.

That equates to the missing 33 degrees of antenna. The wave
that is only 3 degrees back from the tip reflection point

is suddenly only 54 degrees from the current maximum point.

It appears to me that the interference of the forward and reflected waves at the impedance discontinuity causes an actual 33 degree phase shift. How to analyze what happens at such an impedance discontinuity is covered in my energy analysis article at:

http://www.qsl.net/w5dxp/energy.htm

I will try to do that analysis sometime today.

An antenna * system * does not need to have X number of degrees to be resonant. It only needs to have ~zero reactance at its feedpoint -- which, for electrically short AND long radiators can be achieved by use of a suitable matching network.

Such networks don't add or subtract electrical degrees, however. They only reduce/cancel the natural reactance of the physical radiator in use.

I'm not going to bother trying to look it up--but is that not supposed to be something like 8dBm/3kHz BW, or some such? 8dB without a reference doesn't mean much.

If it's 8dBm/3kHz, then the meaning should be obvious: in any 3kHz band there may not be more than +8dBm power (I guess around 7 milliwatts). Spectral density is commonly measured with a spectrum analyzer; many modern ones have band markers that will let the instrument perform a band power measurement.

If you spread 1 watt uniformly over 500kHz, you'd have 1W*3kHz/500kHz, or 6mW, in each 3kHz bandwidth. So the +8dBm limit would mean that the power should be spread very nearly uniformly over that band. (Why did they use units of watts in one place and dBm in another??)

Cheers,
Tom

This is just a guess, but let's see what we can do to make some sense
out of this.

If you were hoping that the 1 watt of power would be evenly
distributed across the 3 kHz bandwidth, that would be for the purpose
of making sure that no one would be putting all of his 1 watt into a
single frequency, which would be quite a strong concentration of power
in comparison to having it spread out over the 3 kHz. The idea being
that the power when concentrated is very noticeable and might cause
QRM, whereas the same wattage spread out evenly over 3 kHz would
barely exceed the background noise and would not be noticeable.

So, you might want to require that signals not be very "peaky", or
concentrated. In order to put limitations on "peakiness", you might
require it to be "at least so wide" and "no higher than x" in units of
spectral density.

Assume that in the above requirement that the 500 Hz bandwidth
requirement is to be interpreted as their requirement that avoids the
signal being concentrated in a narrow band of frequencies. Also assume
that the maximum power density in that 500 Hz bandwidth should be
commensurate with the entire 1 watt being distributed over only 500 Hz
instead of 3 kHz. Notice how we have traded off the requirements so
that they are being applied to 1/6th of the 3 kHz. If we are allowed
to concentrate all of our power in 1/6th of the bandwidth, then it
follows that we would be required to keep the power density in that
bandwidth at no higher than 6X the level it would have when spread out
over the entire 3 kHz.

I find that it is probably not a coincidence that the 6:1 ratio is
almost exactly 8 dB in power ratio.

Hi Jeff,

An aberration was already included in the list of possible outcomes. I did not include such things as you suggest because there was no mechanism to. However, de-ionized water is not that hard to come by, but would certainly lose that characteristic quickly. As de-ionized (and further treated) water has none of the defects you anticipate, I certainly didn't lose sleep in the prospects of its use in HF.

Further, I do have access to a bulk of work employing water loaded antennas (peer reviewed and not just more vanity publishing) that can be used to test reality against theory (as corrupted as it may be by the aberration factor).

I think it's a BIG mistake to be writing about "velocity factor" in this thread (and perhaps also in some current, related threads). The reason is that it presupposes behaviour that is just like a TEM transmission line, and clearly it is not when you get to the fine details. Until we better understand just what is going on, I propose that we simply say that resonance occurs for a wire shorter than 1/4 freespace wavelength, when that wire is fed against a ground plane to which it is perpendicular, and that the thicker the wire, the shorter it is at resonance when compared with the freespace wavelength. The effect can be described with an emperical equation, of course. But to invoke "velocity factor" assumes something about the solution which may well lead you away from the correct explanation.

I don't really expect many will take this seriously--there seems to be too much invested in explaining everything in terms of behaviour that seems familiar. It's a bit like saying a photon is a particle (or a wave). It is not--it is simply a quantum; and it behaves differently from particles we know, and behaves differently from waves we know from our macro-world experience.

The transmission-line analog is a very useful one for practical antenna engineering, just as considering loading elements as lumped reactances (perhaps with parasitic lumped reactance and resistance as appropriate) is useful for practical engineering. But that doesn't mean it fully explains the behaviour in detail.

Cheers,
Tom

A self-resonant coil is obviously 90 degrees long. If one
removes 5% of the turns and replaces them with a stinger
to bring the system back to resonance at the same frequency,
do you really believe the coil has magically changed from
90 degrees long to zero degrees long?

For the feedpoint impedance to be purely resistive, i.e.
resonant, for a standing wave antenna, the reflected wave
must get back into phase with the forward wave. Velocity
factor is a way of explaining how/why that happens. The
diameter of the conductor no doubt appears in the VF
equation.

Go to a new home site (under construction) and pick up a few inches of
PVC 1/2 in. or 3/4 in. cut them to an appealing size and drill some
holes in them at their ends and BAM, insulators!

I like mine professional looking so I buy them from Buxcomm.com. They
are inexpensive and in several designs or styles and Buck got good
prices too!!

A coil is not the electrical equivalent of a linear, physical, ~90-degree, self-resonant radiator. How well do you expect your self-resonant coil to radiate?

When you add a stinger to a coil, it is the stinger that radiates the great majority of the applied power. The coil just makes it possible/practical for the tx to supply r-f power to that antenna system that the stinger CAN radiate, by improving the Z match between the source and the feedpoint.

OK, here is the one for the experienced and theoriticians:

How about antenna made of wires, submerged just below the surface of water, partially salinated (brakish) or sea water. Would it couple to this huge "water antenna" (variations of insulated vs. bare elements) or connect/tap to it?

One experience in this area was, when I operated from VE1ZZ on 160, he has one Eu Beverage that is terminated on the stainless steel hubcap in the ocean. That sucker beats any other "superior" beverages (staggered or phased pairs).

> with your time?

No, I don't know what you mean. And your response doesn't give me a great deal of confidence that you do, either.

The reactance of an infinitely thin half wavelength dipole is 42.5 ohms, meaning that it isn't resonant. An infinitely thin dipole of length 0.496 wavelength, or about 1% shorter, is resonant. So my first question is whether the "true length" of an infinitesimally thin resonant dipole is 0.496 or 0.5 wavelength. (If 1% is too little to quibble about, why are we concerned about a length difference of a wire diameter?)

If we increase the diameter of the antenna to 1/50 its length, the "true length" would then be 1.02 times the "true length" of the infinitesimally thin dipole. Yet we have to reduce the antenna length by nearly 7% to maintain resonance. So the "true length" doesn't have anything obvious to do with resonant length, nor does it provide a way to predict the resonant length based on wire diameter.

If the meaning of "true length" is obvious, most other readers must know what it means. Would someone please be so kind as to explain to me what it means and how it's used?

I don't understand. You're asking about the coupling between a submerged antenna made of wires and a "water antenna"? What's a "water antenna"? How close together are the two antennas?

Any submerged antenna would have to be very shallow if it's to receive signals from above the water -- the attenuation of fields traveling through salt water is very high (~16 dB/foot at 1.8 MHz). If it's very deep, it might as well not be there at all.

1820. "Ocean as antenna"

Newsgroup: rec.radio.amateur.antenna
Date: 2006-05-01 23:32:20 UTC
From: Yuri Blanarovich <K3BU@optonline.net>
Message-ID: <cUw5g.28$br.22@fe11.lga>
Source record: 60059

Let me change the subject, in order not to interfere with original thread.

OK, let me try to elaborate based on what I know and have observed.

We know about the effect of distilled water on submerged radiator, it shrinks the dimensions due to dielectric constant. I am not going to distill the Barnegat Bay.

We know that salt water or brackish water have high conductivity and act to radio waves as reflector and we can take the advantage of this property by using suitable antenna over or next to it.

There is low penetration of such water surface by radio waves, but there should be some RF currents induced close to the surface of said water, (da poor conductor).

The question:
is there concentration of induced RF currents near the surface, and if so, can we tap them by furnishing proper antenna - transducer?
It may be that the whole sandwich of water is just shunted to ground, or is there enough resistance between the ground and surface to allow enough of workable current/signal to collect.
The idea is to "gamma match" the giant "water antenna" which is the water surface, in similar fashion as it is done say with aircraft body surface and a slot (antenna).

I do not remember this mentioned in the books I have and I wonder if it is possible to harness the ocean as an antenna. Jus' wanted to make sure we do not overlook potential "antenna" at our feet.

1821. New program - SKYTRIG

Newsgroup: rec.radio.amateur.antenna
Date: 2006-05-01 23:52:07 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <I8KdnSx2msqRP8vZRVny2Q@bt.com>
Source record: 60061

Program SKYTRIG - SKYWAVE TRIGONOMETRY

With an input of elevation angle, layer height and critical frequency,
the program calculates skywave path distance, groundpath distance,
spreading (dispersion) loss, field strength from a 100 watt
transmitter, and the MUF.

The program can be used for guidance on the low MUF's and the geometry
of near vertical incidence radio paths over short distance
groundpaths.

Elevation angle is NOT the angle at which an antenna radiates the
strongest signal. It is the angle of the path taken by the radio wave
between two places on the Earth's surface and is nothing to do with an
antenna.

The program notes provide some elementary information on the heights
and behaviour of the various ionospheric layers in sunlight and in
darkness. Also on factors which affect received field strength such as
operating frequency being greater than MUF.

Download in a few seconds program SKYTRIG from website below.
Filesize = 42 kilo-bytes. Run immediately. Or you can open/run it
without downloading.

I know perfectly well how to use EZNEC to determine the relationship between the conductor diameter/length ratio and resonant frequency. EZNEC does not tell me anything about "velocity factor" as far as I know. I don't need EZNEC to tell me the resonant-frequency and conductor diameter/length ratio relationship; I have that in detail from other sources. Those sources also don't tell me anything about "velocity factor" as far as I can tell.

I don't expect those who are totally invested in and entangled by "velocity factor" to understand this. But they continue to fulfill my expectations. (Richard C. will probably even predict with some accuracy their next card to be played...)

Cheers,
Tom

Hi Yuri,

Certainly. More so above the surface than below. It stands to reason
as that was the best way for it to get beneath the surface by coming
in from above. Now, if you are searching for another trapped layer
for RF, you have to allow that seawater is pitifully lossy even if it
does present a huge shiny interface. Anything "trapped" in it is
consumed by it in very few feet.

An RF wave has to overcome a huge mismatch to get any power into the
sea. Over the entire HF band that SWR is a minimum 19:1. In the 160M
band the SWR is 75:1.

Indeed...

And--how is the resonance affected by using a tubular conductor that's open on the ends? What if the bottom end of a monopole fed against a ground plane (or the meeting ends of a doublet) is conical with perhaps a 30 degree included angle, out to the uniform diameter of the tube? Does it matter whether the upper end (outer ends) of the tube is open or has a disk shorting across it? (A wire-frame simulation suggests that a disk shorting the top has a small effect, but less than half its radius.)

But certainly as Roy says, the effect on resonance is much greater than considering the length to be one diameter longer than the end-to-end length of the conductor.

These aren't details that are likely to matter in a ham antenna installation, but they are interesting to me from a theoretical point of view.

Cheers,
Tom

1826. Re: "Ocean as antenna"

Sorry for the top post.

can the premise be restated as follows:

"Could an insulated wire in a lossy conductive medium [AKA ocean water]
near the surface be modeled as a slot antenna in a lossy plane?"

+ + +

and...
if there is such an effect what is the best way to "catch the RF waves"
grazing the shining ocean surface. More like - can it work besides just
being modeled?

I have been using "dog loop" antenna, originally RF dog fence around 3/4
acre lot, which is basically wire loop burried about 1 inch below the
surface. It has about 600 ohms and works like a goofy Beverage, low noise
pickup and still delivering reasonable signal on 80/160. That's why this
bugs me, like using floating antenna?

Just wondering if there is any potential in this or if anything was written
up in the antenna books pro or con.

C even goes negative for smaller values of Length/Dia.

I'll let you into a secret - the formulae are approximate and don't
apply when antenna length is less than about 5 times its diameter.

When was the last time you saw an antenna wire only 5 times longer
than its diameter?

1833. Re: A little more on missing degrees

Richard Fry wrote:
"Such networks don`t add or subtract electrical degrees, however. They only reduce/cancel the natural reactance of the physical radiator in use."

True if the only mismatch is reactance. A too-long antenna can be electrically shortened for matching purposes by tuning it to resonance with the proper series capacitance. A too-short antenna can be electrically lengthened for matching purposes by tuning it to resonance with the proper series inductance.

Reactance varies quickly near the resonant length. Radiation resistance varies more slowly tending to increase at a steady rate as the antenna is lengthened.

What radiates is current in a length of antenna. What gets current into an antenna is a conjugate match. Reactance is zeroed out, and source and load resistances are matched. That`s what`s needed for maximum power transfer between generator and antenna.

Analysis may have been more abundant than needed for practical purposes.

The velocity of current through a coil has been disputed. Some said it was almost instantaneous. That was new to me. The nature of inductance is to produce counter emf which by Lenz`s law opposes current into an inductance and temporarily delays current changes in an inductance. Only in a pure resistance is there instantaneous correlation between voltage and current.

It is believed that the speed of light "c" is a speed limit on electromagnetic waves. An action in one place must have a delayed response elsewhere depending on distance.

I can imagine a wave launched at one of an inductor sweeping across its length and ignoring the round and round path of the wire, but I don`t know of any of the old authors in my collection who say that such a short-cut happens. Conductors are the source of free electrons which permit current flow and my experience is that electricity goes where it is wired.

Best regards, Richard Harrison, KB5WZI

No. To my knowledge, a slot antenna requires a thin plane, which an ocean doesn't resemble. I imagine you could make one in a solid like a chunk of metal, but believe that the hole depth would have to be a substantial fraction of a wavelength.

Not sure what effect you mean. But NEC-4 models interactions at, above, and below a medium like water with reasonable accuracy.

I think you'll find that a buried antenna will work more and more poorly as the ground conductivity gets better and better. As an extreme, how well do you think it would work if buried in an Earth-sized chunk of metal?

> Just wondering if there is any potential in this or if anything was written
> up in the antenna books pro or con.

I think you're on your own. The path is clear for you to be the first to make great discoveries! Just be sure to take a little time off along the way to do make those coil measurements.

Harbin,

When the USA Constitution was written there was NO government! There was a group of independent states. No government higher than state government in existence. All state governments were equal.

The USA Constitution begins: "We the People..." not "We the citizens..."

Rights, ALL RIGHTS belong to the people. If you studied philosophy, you would conclude that rights are rooted in the dignity of the person, not derived from government. Government responsibilities and authority are delegated from the people to the government for the maximum common good for the maximum number of people.

1841. help with rotor brands

Hi All,
I'm searching for a rotor to use with a Flag antenna (as in Flag/Pennant).
At present I'm using an Alliance U110 tv antenna rotor.
I'm rebuilding my Flag and it will a bit heavier and has lots of leverage,
15ft each side of the mast. The tv rotor seems to have been fine in the past
but I need a control unit that is SILENT. The Alliance control unit does
the Clunk, Clunk, Clunk as the mast rotates.
I don't know any brands or specifications so all info is appreciated.
Thanks
Mike

PS. Is there a group or reflector that might
be a better resource for this question?

From
http://www.mso.anu.edu.au/cas/presents/don.html

I quote
"Joe Pawsey took me up to Dover Heights that first day to the cliff-top interferometer. It was a very cunning device. As the sun rose above the ocean there was a reflected ray off the ocean, received by the antenna, and then the direct ray; this formed an interferometer - like a Lloyds mirror type thing - this was the array that found that the Crab Nebula was a radio source, and also did much of the early work on Cygnus"

> Cheers,
> Tom
>
==========
Yes, the velocity factor doesn't change with Length/Diameter. But it
is sometimes convenient to discuss the effect as such.

Actually everything happens at and near the ends of the wire. The
short length of wire to be pruned to bring about a state of resonance
is the same regardless of the number of half-waves in the anenna.

It is sometimes referred to as the "End Effect".

Think in terms of the directions of the electric lines of force at the
wire ends. They are not all radial lines of force. Some of them
extend outwards in the direction of the wire. In the same way as
magnetic lines of force appear when a bar magnet is sprinkled with
iron filings.

This, at the ends, and only at the ends, has the effect of increasing
capacitance to the rest of the Universe. The wire behaves as if its
longer than it actually is. Hence pruning is necessary.

When several half-waves are connected in series it is not necessary to
prune each of the half-waves. The electric lines of force are all in
radial directions at their junctions.

The "end-effect" occurs with any length of antenna. There are only two
ends. Obviously, as the diameter/length ratio increases so does the
effect. The flat ends of the antenna support a greater number of
lines of force in line with the antenna.

The effect slightly reduces efficiency. When the antenna is pruned to
bring it into resonance it is accompanied by a reduction in radiation
resistance. This is most noticeable at UHF and above where very fat
cylindrical antennas are used. Sometimes elipsoids are used for high
power transmitting antennas.

I trust my description/explanation has not further confused the issue.

Reg.

Hi Group,

D-link has a vertical antenna for WiFi applications which is about a foot long and operates at 2.4 GHz with a stated 7dbi gain.

Since the antenna is a vertical, I thought that the best low-angle radiation is 5/8 wave for verticals, anything longer would put the lobes higher and would result in a lower low angle gain.

If this is the case then the antenna should only be about 3.5 inches long. ?

I am going to check, but I bet the true antenna is only about this lenght and the rest of the lenght is the plastic, so the appeal is bigger is better.

Any thoughts on this?

> self-resonant coil to radiate?

Not very well. Nobody is saying that a coil is a good
radiator. It probably radiates about as much RF as a
piece of wire of the same axial length as the coil.

Nothing about the discussion of phase
shift through a coil has had anything to do with radiation.
In fact, I have ignored radiation from the coil in all
of my calculations since I consider it to be negligible.

We have a phase shift in a transmission line with negligible
radiation. The same is true of a loading coil.

> When you add a stinger to a coil, it is the stinger that radiates the
> great majority of the applied power.

Absolutely no question about that. The round and round
design of a coil makes it more akin to a piece of
transmission line than it does to a radiator. But like
a transmission line stub, it contributes a phase shift
to the system.

The stub on a properly designed J-Pole doesn't radiate
much either. But one can certainly calculate the phase
shift from the feedpoint to bottom of the radiating element.

Again, the phase shift in the coil has virtually nothing
to do with how much the coil radiates. Looking at just
one turn on the coil, the current on each side of the
turn is approximately equal magnitude and flowing in
opposite directions (just as in a transmission line).
So virtually all the radiation is canceled by the
opposite near fields (just as in a transmission line).

Fine. From now on, I will assume you have no time to explain your "secrets"
when you post so I will ignore your formulae. This approach is much better
than being misled if I do not read between your lines properly.

What RF engineers call "velocity factor" is related to the phase constant in the complex propagation constant embedded in any transmission line equation in any decent textbook. Do your sources tell you anything about the complex propagation constant?

> is wired.

Consider a tank circuit link coupled to the outside world.
There are probably negligible free electrons flowing from
primary to secondary. Yet efficient energy transfer occurs
when the coils are tightly coupled.

In a loading coil, each turn is tightly coupled to the
adjacent turn causing part of the current to be the result
of the fields rather than wire path. That's why the VF of
the loading coil is roughly double what it would be for
"round and round the coil" calculations. The VF for a 75m
bugcatcher coil appears to be in the ballpark of 0.04 which
is a far cry from the straight across 1.0 or even 0.5

The working definition of "elevation angle," of course, depends on the
context. Your definition is appropriate in the context of your program,
and for propagation ray tracing.

But the moonbouncer would generally mean the elevation angle of his
array (or the moon), the static array designer might well mean the angle
of his maximum lobe, the aircraft spotter would mean the angle of the
target, the artilleryman would mean his muzzle angle, and so forth,
and so on.

Hi Dave,

You are quite wrong. Previous to the ratification of the U.S.
Constitution, we lived under the Articles of Confederation which was a
Republican form of government complete with assembly and President.

The Constitutional Congress was formed to look at the Articles, not
create a new government.
>
>The USA Constitution begins: "We the People..." not "We the citizens..."

The Constitution speaks of citizens of states, but it nowhere provides
for the qualifications of becoming a citizen. However, there is the
3/5ths rule and the untaxed Indians who are implicitly not citizens
(saying nothing of women).

>Rights, ALL RIGHTS belong to the people.

There are many in the current administration that would dispute this.

Cec, I do wish you would stick to metric dimensions instead of feet
and inches. It would make life much easier.

You've read about it in a book. Have you ever measured it? Has
anybody else ever measured it?

Although a continuous loop has no ends it does have a small opposing
mutual impedace (both L and C) between one side of the loop and the
other. This affects the velocity factor. The mutual impedance does
not exist when the wire is all in one straight line.

What explanation do YOU have to offer?

Reg.

PD-

The beauty of the 5/8 (0.625) wavelength groundplane antenna, is that its feedpoint impedance has a resistive component of 50 Ohms, and can easily be matched with a small inductor. Some such antennas have been constructed by winding the coil using the base of the antenna rod. It is my recollection from an antennas class 35 years ago, that the best signal towards the horizon comes from a 0.58 wavelength groundplane antenna, not 0.625 wavelength. I can see how 5/8 and 0.58 might be confused, and many may consider the difference trivial.

As far as the D-Link antenna, it is most likely a co-axially fed vertical dipole with additional colinear elements separated by phasing networks.

Fred

The RF effect is probably not much for transmitting, but receiving may pick up lots of noise. It all depends on what type of power line you are refering to. If it's a single distribution line in a residential area, it will relatively low voltage and noise. If you are looking at a high voltage feeder line with multiple 3-phase lines, then you will get lots of noise, including corona discharge, arcing when the insulators are wet and dirty.

My 160 meter dipole has one end near a line with two high tension feeder lines plus the residential feeder line. I use the antenna on all bands, and can really hear the noise reduction when on 40 meters and above and switch to an antenna quite a way from the power lines.

My power company also has a deeded right of way along the South part of my property where I cannot put anything above a certain height or build anything that might contact a falling wire. If this is your case also, you might take a look at your deed restrictions and put your poll outside the restricted area.

Good luck, Paul KD7HB

Hello, and there appears to be faulty logic here. Any other form of chart not in Smith's format or variants thereof (e.g. a Carter Chart) cannot be a Smith Chart. The fact that Phillip Smith's and similar types of charts are all based upon the transmission line equations is irrelevant to giving due credit to their respective developers. Smith recognizes (pg xv, intro to Smith's book) that similar charts (and their respective limitations) formulated by others inspired him.

Do we say that since a couple of brothers from Dayton, Ohio leveraged then-existing aviation technologies and ideas developed by others (e.g. gliders) the Wrights shouldn't be given credit for inventing a successful human carrying, heavier-than-air, propeller-driven aircraft?

And for the flip side, while many readily identify Marconi, DeForest, J. Fleming and sometimes Tesla as radio pioneers how many can recall Edwin Armstrong? Sincerely, and 73s from N4GGO,

The Articles of Confederation were a failure! No centralized government. The USA government, as we basically have it today did not exist during and after the Revolutionary War. The Constitution did not become the Law of the USA until 4 March 1789.

The Amendments are written as follows:

Prior to ratification of the Constitution, Amendments 1 through 10 use the language of 'PEOPLE' [not citizen]. [Amendments 1, 2, 4, 5, 9, and 10] [Prior to 4 March 1789]

Subsequent to ratification of the Constitution, Amendments 11 through 26, that deal with human, not political or liquor issues, use the language of 'CITIZENS'. [Amendments 11, 14, 15, 17, 19, 24, and 26]

The 14th amendment, following the US Civil War [9 July 1868], establishes citizenship definitions as follows:

"1. All persons born or naturalized in the United States, and subject to the jurisdiction thereof, are citizens of the United States and of the State wherein they reside." This was originally worded to assure citizenship to the emancipated slaves. It has since been judicially interpreted in a broader sense.

In the current passionate discussion of immigration rights we categorize and pre-judge, by our use of language, a group of people. Are they 'Illegal Immigrants', or, 'Undocumented Workers'? Regarding the law governing immigration, is it founded on 'per ipse 'wrong or is it founded on 'Good Order for the maximum common good'. I suspect the number of immigrants from any nation who may legally immigrate to the USA is arbitrarily chosen in the US House of Representatives. The quotas can be easily changed by act of Congress. A case can be made that QUOTA systems are basically discriminatory.

Regarding the 'oppressive' states, and there are many, the politics of 'Power' and 'Might makes Right' does not ratify the yearning of people to be FREE. Governments may and do usurp human rights, but that does make it right! The UN has an Office of Human Rights. The Pope has an Office of Human Rights. Many governments of Europe have political entities devoted to Human Rights. There are many NGOs devoted to human rights. These rights include fundamental human rights, political rights and social rights.

IMO, secure borders, in a post 9-11 USA environment, cannot be morally justified based on QUOTAS. And we have quotas for the Mexican immigrants. How are these quotas justified? [Does the USA authorize 100,000, 500,000 or 1,000,000 immigrants a year? Why is there any

particular number?]

I'm pontificating, I know it! But, I see injustice in any QUOTA system.

/S/ DD, W1MCE

Yes, and I work with one, and support many. However, few of these
agencies that you offer have the power to open borders.

>IMO, secure borders, in a post 9-11 USA environment, cannot be morally
>justified based on QUOTAS.

We have always had quotas with and without the 9-11 context. It seems
odd to separate them from the morality equation.

>And we have quotas for the Mexican
>immigrants. How are these quotas justified? [Does the USA authorize
>100,000, 500,000 or 1,000,000 immigrants a year? Why is there any
>particular number?]

Justified? The courts answer to that as it is their business. OK, I
can tell what you mean by "justified" but you are freely mixing
morality, laws, government, and history and the meaning of "justified"
goes through a great amount of flexibility to support any one
argument.

>I'm pontificating, I know it! But, I see injustice in any QUOTA system.

Any quota system? The apportionment of members of congress by
population is just one system.

There's an obvious quota in the ability of border guards to simply
look at every visitor coming across the border. A line waiting to be
seen is its own quota. If you did less than simply look, then yes, we
would be quota free. Would it be unreasonable to have a guest book at
the border for everyone to sign, or would this be a quota too?

No, pontificating is not a solution and seeing injustice is not really
being a witness.

Thanks, Reg. It certainly didn't 'further confuse' the issue for me, though I can't speak for others.

Never one to let things rest without doing a bit of thinking about them, I had a look at some info I have from R.W.P. King, and also did a bit of NEC2 simulating. What I find is that for half-wave and 3/2-wave dipoles, the shortening effect is nearly the same length (constant frequency and wire diameter), but for full wave and 2-wave long antennas, the shortening is greater. King and NEC2 agree pretty closely for the half and 3/2 case but differ noticably for the full and 2-wave case, though again, the shortening is (somewhat more roughly) the same for a given model when comparing the full and 2 wave cases.

I suppose the difference between the models, and the difference between the resonant (odd-half-waves) versus anti-resonant (even-half-waves) cases, can be accounted for by the terminal conditions. After all, the electric field is quite high at the center feedpoint of the even-half-waves antennas, so details of the terminal conditions (wire diameter and spacing) are important there, much more so than with the relatively low electric fields in that region for the odd-half-waves antennas. The terminal conditions act roughly like a capacitor across the feedpoint, and that has little effect with the low feedpoint impedance of the odd-half-waves antennas, but a much larger effect with the higher feedpoint impedance of the even-half-waves antennas.

I also used NEC2 to simulate the effects of a small top-hat: it was 4 radial wires at the top of a vertical, 0.001 wavelengths long. The vertical diameter was .000001 wavelengths (as were the radials forming the top hat). I found that adding that top had reduced the length for resonance by exactly the same length in each case, for 1/4, 2/4, 3/4 and 4/4 wave tall antennas, probably within the accuracy of the computing engine. (The differences among the shortenings was less than 0.01% of a wavelength; the shortening effect of the top hat was 0.4%.)

I suppose there are some higher-order effects going on too, but this is close enough to satisfy my curiosity--for now. Thanks to Pierre for posting an interesting question that has nothing to do with "velocity factor."

Cheers,
Tom

> may consider the difference trivial.

Maximum gain at the horizon actually occurs at around 0.625 wavelength. At lengths between 0.5 and 0.625, a higher angle lobe appears, but it doesn't divert a significant amount of the total power away from the main lobe until the antenna gets longer than 0.625 wavelength.

However, those gain figures are for a vertical antenna mounted on a perfect, infinite, ground plane. Actual performance of 0.5 or 0.625 wavelength antennas compared to quarter wave ones varies a great deal in most typical situations. And any kind of WLAN device I've seen deviates in major ways from the ideal case. Gain of a longer antenna is as likely to be due to placebo effect as to physics.

One big advantage of a 0.5 wavelength antenna is its high feedpoint impedance. This makes it much more independent of the other half of the antenna -- what amateurs like to call "ground", but is often the top of a car, a person holding an HT, a router box, etc. The advantage isn't shared by the 0.625 wavelength radiator.

Source record: 60107

Dear Group:
The use of one number is crude and suitable only if one has imbibed enough grain alcohol or one does not care about Lord K's admonition or both.

The preferred scheme is to model the expected virtual heights at each ionospheric reflection (note that the apparent TOA (angles) involved are not likely to be the same at each of these reflections) and then to use the angles involved to note the expected incidence angle of the intermediate "ground" reflection. The coordinates of the expected "ground" reflection areas are calculated and note is taken as to whether those areas are predominately salt-water, ice, or neither. A heuristic algorithm is applied that depends on type of "ground" and that weakly depends on the expected incidence angle. The result is a statistically significant reflection loss. [Some iteration is needed, which computers are very good at doing.]

It is important to note that the apparent TOA of the major mode between two points is unlikely to be the same at both ends of the path because the virtual height is unlikely to be the same near both ends.

For HF paths greater than something like 12 or 14 Mm predictions become more complex. In all cases of multiple hops (real DX), the TOA at which the gain of the antennas is effective varies between about 12 degrees and 2 degrees.

If one wishes a simple predictor, one could find it in a paper published in the UK in the transactions on a conference on HF propagation in the 80s (as I recall) by a BBC engineer (IEE was the publisher). The entire computer code is given in the paper. It uses a simple heuristic model that was found by the BBC to give satisfactory results over the paths that their World Service used. Note that the BBC used paths that did not include much of the polar regions.

To digress: The worst path to a DXCC entity from the Upper Midwest is over the magnetic pole to VU4. 100 watt transmitters, ice reflections, heavy absorption, and roughly 10 db more noise at the far end make the need for power and high antennas almost necessary.

There's another interesting thing about very fat antennas.

Again considering them as transmission lines, their Zo is quite low
and so the input, or end impedance of a half-wave dipole is relatively
low.

Thus it is possible to place two half-wave dipoles in series and feed
them in the middle. (In the same way as feeding one half-wave dipole
in the middle).

What does the radiation pattern of a full-wave, exceedingly fat dipole
look like? Can the modelling programs cope? What's the feedpoint
impedance at resonance? What's the bandwidth?

What about a 4 or 5-to-1 ratio for Length / Diameter?

Reg.

"End effect" looks to me like a description of a result, not an explanation of a cause. Its "proof" consists of the observation that fatter dipoles have a shorter resonant length than thin ones. I'm afraid a real explanation of why the "end effect" occurs requires much deeper physics and math.

I don't believe that Tom's result with the top hat is a demonstration of the same phenomenon that makes resonant fat dipoles shorter than thin ones. Here's what the top hat experiment means:

Suppose you have a thin antenna of any length. Look at the current distribution on the last few degrees of the antenna. I believe you'll find that it's the same regardless of the antenna length. Then replace the wire with a top hat. Again you'll find that the current distribution on the top hat is the same regardless of the length of the antenna below it. So it shouldn't be surprising that you can substitute one for the other and get the same result regardless of the antenna length.

This proves that you can replace a part of an antenna with a capacitive hat, and that the relationship between the length of wire and size of top hat is, at least to first order, independent of the antenna length. It's not clear to me what else it proves.

Incidentally, does this have anything to do with the "true length" of an antenna? No one has stepped forward yet with an explanation.

For a 1/2WL dipole, it is also the same at the center of the
antenna and at all other points anywhere on the antenna. The
standing wave current phase cannot be used to measure phase
shift in a wire or a coil or a top hat or a stub. The phase
of standing wave current is meaningless.

If one makes the top hat large enough, one should see an
abrupt ~180 phase reversal in the standing wave current.
This happens on each side of a current minimum point.

That`s an indication that they knew something about broadcasting. There must be a better way somewhere that doesn`t involve a path near a polar region.

A broadcaster must advertise his programs well in advance. He can`t find a band that`s open and tailor his emissions to it. He must fire up on schedule with the right program at the designated time and direction regardless of conditions. All is planned long ahead of time.

One of the most usless toys we had was a backscatter ionospheric sounder. It worked well but we had no immediate need for the information it provided. We were locked in our schedules for months in advance and today`s ionospheric conditions were short-term indeed.

A good argument for moving international broadcast to the VHF/UHF or higher regions. HF was good when there were no alternatives, but the time has come to retire it.

Polyester or polypropylene? The polyester is pretty good even without
the black UV resistant layer. Polypropylene frizzes, fades and gets
weak very, very quickly.

One of the very good things about polyester rope is that it doesn't stretch much at all--let's say, compared to nylon rope which stretches a great deal.

Where is your rope breaking and what is it attached to? I use plain old nylon 1/4" rope to support the end of my inverted L for 160m. The far end runs though a nylon pulley attached to another rope up in a maple tree. The rope attached to the antenna runs down the tree and is attached to an old window sash weight. The weight is free to bob up and down with the swaying of the tree. That keeps the rope and antenna wire from breaking.

> I've been using black plastic eggs sold for electric fencing apps.
> They've worked well for about 5 years now.

They're likely a little short for high power, Mike. You might consider using a couple of them at each end with a short piece of nylon rope in between them. I use the black plastic "nail-on" fence insulators for running a beverage antenna down a tree line. They are cheap and they work well. The have a snap-in retainer so they're easy to re-use if the aluminum fence wire I'm using should ever break.

I use those Hy-Gain center insulators made of black plastic with rubber membrane and stainless screws and nuts. They never seem to fail and certainly keep water out of the coaxial cable. Ten-Tec is making their little Acro-Bat center insulator. It is good for 300 ohm window line and RG-58 but they don't make a model for RG-213-sized cable.

OK. I wqas thinking of weak but undistorted signals - there seems to be
evidence that digital modes can get through when CW can't even be heard.
Audible but distorted signals, as you mention, are a different problem,
one that I wasn't thinking of. Sort of like those distorted letters you
have to decypher to gain access to restricted Yahoo groups, GoDaddy
domain information, and various other web sites - a machine can
certainly see them, but OCR isn't good enough to read them (neither am
I, sometimes).

I agree with Roy on this, that an accurate understanding will take some fairly serious analysis. For example, the top hat in my example had _less_ shortening effect than simply using a wire with radius only 1/4 as large as the length of the top hat radials. Also, calculations of the capacitance of a spherical capacitor, compared with capacitance per unit length of the antenna wire, don't give me any confidence that the end capacitance fully explains the shortening effect.

Cheers,
Tom

The Sept/Oct 2005 issue of QEX has a 4:1 balun design that may
interest you. It can be found on the ARRL's members only web site.

Would a 4:1 voltage balun fed through a husky 1:1 choke
(W2DU BALUN) accomplish the same thing?

The single core designs are usually voltage baluns and
what we hams want are balanced currents. I don't see
why you couldn't just add a husky 1:1 W2DU style choke
on the 50 ohm side of your 4:1 voltage balun to inhibit
common mode current. The extra toroid in the afore mentioned
QEX article is a 1:1 choke attached to a 4:1 voltage balun.

For those who didn't give up, here is a summary of what I
was able to do with EZNEC. This exercise should be able
to be repeated in the real world.

1. Using the helix feature of EZNEC, I created a 100 turn
octagonal coil, 6 inches in diameter, 4 turns per inch.

2. I installed it as a base loading coil over a mininec
ground plane and removed turns until it was self-resonant
on 4 MHz. That left a total of 69 turns on a 1.435 foot
long coil. Give that the coil is 90 degrees at the self-
resonant frequency, I calculated a velocity factor of
0.023 for the coil.

3. The coil was then trimmed to half size, i.e. 34.5 turns.
Assuming it was then 45 degrees long, the Z0 was determined
to be approximately 2200 ohms by looking at the feedpoint
impedance reported by EZNEC. 45 degrees from 0-j0 on the
Smith Chart is at -j1.0.

4. A stinger was added to the above 45 degrees of coil to
bring the antenna back to resonance on 4 MHz. It took 7 ft.
of stinger, or 10.2 degrees. 10.2 degrees from 0-j*infinity
on the Smith Chart is at -j4.8.

5. The ratio of -j4.8/-j1.0 is the ratio of the Z0 of the
coil to the Z0 of the stinger. If the Z0 of the coil is
indeed 2200 ohms, the Z0 of the stinger is 458 ohms, just
about where it should be. The impedance discontinuity
provides the "missing" ~35 degrees of the antenna.

6. Using Dr. Corum's equation for velocity factor yields
0.02 for that coil, a value 13% lower than the one
predicted by EZNEC, well within the ballpark for
expectations.

My conclusions: The delay through a loading coil is in
the tens of degrees. The delay through the elements of
the antenna do not add up to 90 degrees. In the above
EZNEC example, the delay from feedpoint to the tip of
the antenna is only 55 degrees. The "missing"
degrees are provided by the impedance discontinuity
between the coil and the stinger. There is no real-

time delay associated with those "missing" degrees.

Now it makes more sense. :-) What is scarey is that some
browsers may display Greek characters correctly and some
may not.

> What kind of bait are you throwing out about SQRT[Z*Y] ?

Z is the distributed series impedance and Y is the distributed
shunt admittance. The equation for the propagation constant
is gamma = alpha + j*beta = SQRT(Z*Y). Doesn't multiplying
an impedance by an admittance result in a dimensionless
quantity?

No - that is not correct, in my opinion. My interpretation is that the
spectral power density in a 500 Hz bandwidth must not exceed the limit
of 2 milliwatts per Hz. (Simply spread the 1 watt over a width of 500
Hz.
In my original post I thought your message said 500Hz. Now I see you
are saying 500kHz. Which is correct?

>what if i use 6khz or
>5khz?does proportionality hold here or just say in any bandwith not
>greater than 500khz, the peak power level should not always exceed
>8dBm?..

The 8 dBm is a red-herring. I took your value of 8 dB as Gospel. If
someone says 8 dB they don't mean 8 dBm and vice versa.

Can you make sure of the accuracy of your excerpts, because I see
nothing in the Part 15 regs that correlate with your numbers.

In other words, I'm working with nothing but your excerpts and common
sense electrical engineering.

In item 2 you make an unsupported statement: "Give that the coil is 90 degrees at the self-resonant frequency,..."

Self resonance only means that the capacitive and inductive reactances, both distributed, are equal. That does not validate a 90 degree assumption. Without that validation, IMO, the subsequent discussion is questionable.

Single core baluns do work in the sense that they will pass signals without strong attenuation in most cases, they will transform impedances properly, and they are broadband. They will work well in a system that is already fairly well balanced.

You will need to evaluate your application as single core 4:1 baluns have the following disadvantages compared to, say, the 4:1 Guanella two-core current balun:

1. They do not supress common-mode currents well.
2. They require a larger core to work with a given power in a fairly well-balanced system (a severely unbalanced system might have to be evaluated more carefully to determine core size).
3. When properly built with a core that couples most all flux to all windings, the single core balun will have no output into a fully unbalanced system. An unbalanced system is one where either end of the load is grounded. A balanced system is one where the load is grounded in the center. There is also a floating system where the load is not grounded at all.

They have the advantage that they only use one core.

On an antenna, the effects of using a voltage balun (all single core 4:1 baluns seem to be voltage baluns) instead of a current balun can be subtle or even undetectable. My experience with an offset fed dipole was that the antenna receive signal-to-noise ratio degraded under some conditions without a current balun in place (maybe simply because the pattern was different). Adding the current balun helped, and the antenna tuned a little more as I expected it to on the higher bands. My feedline is near a huge aluminum siding slab, and I think there was some effect from that.

An offset fed dipole can be pretty unbalanced, though. Other antennas might do just fine with a single core balun.

I'm sure others will add their comments, and perhaps disagree with me. This has been a controversial subject in the past, but more recent discussions have been better.

Constraining the discussion to lumped circuit theory, the delay that you speak of would seem to be relevant if one is measuring transient response. However, for a steady-state a.c. current, is it not more appropriate to describe the relationship as a phase lag between the current through and the voltage across the inductor? Further, is it not the case that such phase difference is nominally fixed at near 90 degrees (for a high Q inductor), and is it not true that the velocity is nonetheless at the speed of light?

Quoting from the Corum paper concerning self resonance
of a coil:

"The forward and backward traveling waves have superposed
to give this voltage standing wave distribution along the
resonator. There is a voltage null at the base, a voltage
maximum at the top, and a sine wave envelope along the
structure." That defines 90 degrees of coil.

For the standing wave, there are 90 degrees between a voltage
null and a voltage maximum. The voltage maximum at the top
of the coil corresponds to the current null existing there
because the current has no place to go. The voltage null at
the base corresponds to the current maximum there which is
a necessary condition for self resonance. There's 90 degrees
between a voltage null and a voltage maximum. There's 90
degrees between a current null and a current maximum.

I forgot to mention: using a voltage balun on an antenna can have RF-in-the-shack implications. A 20M folded dipole I once built with a 4:1 trifilar wound voltage balun was terrible even though it was center-fed. Tuning was extremely touchy and removing my hand from the tuner knob would detune the antenna. I did not try a current balun on that antenna and it is history now. Maybe some one else has had simialr experience.

1897. Measuring quarter wave cable length with HP 8405A

Newsgroup: rec.radio.amateur.antenna
Date: 2006-05-03 16:37:00 UTC
From: Gary Schafer <gaschafer@comcast.net>
Message-ID: <3omh52p0s8ch01bocrb8l3bgbd2deg5en9@4ax.com>
Source record: 60136

I am using an HP 8405A vector voltmeter to try and measure the delay
in a transmission line in the 2 meter band.
This is part of a phasing harness for a pair of 2 meter antennas to
put them into circular polarization.

The set up is as follows: A T connector on the signal generator with a
pair of 75 ohm ï¿½ wave length jumpers from either side of the T. At the
ends I put an adaptor and a bnc T connector of which one side connects
to the probe of the 8405A and the other end of the bnc T is a 50 ohm
load.
The other 75 ohm ï¿½ wave jumper has the same setup with the bnc T, 50
ohm load and B channel probe of the 8405A.

With this I see a zero degree phase difference on the 8405A as it
should be.
Then I insert a ï¿½ wave length 50 ohm cable between one of the 75 ohm
cable ends and the bnc T connector / 8405A probe connection point.
There are the same number of adaptors in each side of the lines. The
only addition is one barrel connector and the ï¿½ wave length of 50 ohm
cable. (this is in the B channel by the way)
The additional barrel connector is part of the ï¿½ wave length on the 50
ohm line.

The wanted frequency is 145 Mhz.
Rather than seeing 90 degrees delay with the added 50 ohm line section
I only see 60 degrees of delay?? If I run the frequency up to around
180 Mhz I get the 90 degrees delay shown on the 8405A.
What do you suppose I am doing wrong in the measurement setup?

I have measured the delay on the 50 ohm line section by itself (with
the one barrel connector) and I see 90 degrees of delay at 145 Mhz. I
used 20 db pads on each side of the T from the signal generator to
isolate the two sides of the test setup when measuring this cable by
itself.

Thanks
Gary K4FMX

I don't understand the description of the test setup so
this may be a stupid question but what would a 50 ohm
SWR meter read if installed in that 50 ohm line during
the test?

Unless you can see the wire, it may not just have a single radiator. We used
some Andrew 2GHz antennas at work that were about 3 feet long, and an inch
thick. I believe it was made up of multile 1/2 wave phased radiators.

SQRT[Z*Y] = SQRT [[Z11 + jZ12]*[Y11 + jY12]] = Z11*Y11 - Z12*Y12
+jZ12*Y11 +jY12*Z11 [I think I got all the terms correct.]

So, the attenuation constant is still a complex number and it is
dimensionless.

In the transmission line equations the attenuation constant is
multiplied by line length yielding an expression in Nepers
[dimensionless] and radians [dimensionless].

Under that definition my 8 foot high mobile antenna has a voltage maximum at the top and a current maximum at the base and must, therefore, be 90 degrees long. But, it is physically only 16 degrees long [8/43.5 @ 5.37 MHz]. Now it is 5 degrees long above the top of the coil and 10 degrees long below the coil ... ad nauseum [for another 2 months] ...

Where is the other 74 degrees?? This is the question that started this 2 month discussion.

Is there a fallacy in Corum's paper?

Does Corum's paper apply to a combination of a loading coil and radiating elements?

My reasoning is as follows: if I draw a phasor diagram, I have +10 degrees phase shift from the feed point to the base of the coil. I can then assume a +90 degree phase shift in the coil, classical inductive response; then, the 'stinger', from the top of the coil to the tip of the antenna produces a net -10 degree phase shift from both inductive[+] and capacitive[-] effects resulting in a net 90 degree phase shift for the full eight foot antenna.

Am I being too simplistic?

I conclude that I have a 16 degree long antenna with a feedpoint resistance of ~13 ohms [Rr = ~1.0 ohm and Rloss = ~12 ohms] with zero ohms reactance [resonant]. [And that the phase shifts stated above are fundamentally correct.]

Presumably you meant "propagation constant" (which is anything but constant for real lines). In any event it is most certainly is not dimensionless. If it were and you multiplied it by a length, your result would have units of length. Oh, and I think you left the sqrt off the right side of the equation. I guess Z11 is resistance per unit length, Z22 is the radian frequency times the inductance per unit length, etc?? Sigh.

Cheers,
Tom

Dave wrote:
> Where is the other 74 degrees??

Please reference my other postings. It is all explained
there.

1. There are tens of degrees in the coil. That phase shift
is not instantaneous and obeys the VF of the coil.

2. There are tens of degrees in the impedance discontinuity
between the coil and stinger. That phase shift is instantaneous
and requires no delay.

3. There are tens of degrees in the stinger. That phase shift
is not instantaneous and obeys the VF of the stinger.

4. They all add up to 90 degrees.

Hi all,

I'm Alexander and I'm a total newbe of radiofrequency comunication.
Fortunately I have a little knowledge of physics.

Now, my problem is: I want to record a raw UHF signal.
First step: I need an antenna. Any suggestion (web HowTos, pdf or anything alike)?
Once I have the antenna and the circuitry behind it, I'd need a means of recordingWhen I was at the university we had some nice toys which were able to create (wired) digital signals. No I suppose there also are spectrum analizers which could transform an analogic signal from the antenna to a digital one so it can be easily recorded on a pc. Unfortunately I don't even know how they are called! :-/ I called them ADC (as opposed to DAC), but never heard this term actually. Could you give me a track to follow?

Thanks to anyone so kind to help,

Alexander

Something is not as it seems. I think I understand your setup; the ends of the 75 ohm lines both see 50 ohms when you're measuring, in both the zero degree "calibration" phase and with the measurement of the 50 ohm line inserted...assuming it really is 50 ohm line (though that shouldn't make a difference anyway). I assume you've tried swapping probes, and you see the 60 degree phase shift the opposite direction? The phase shift of 30 degrees going from 145 to 180 doesn't sound right: it sounds like the phase shift across a resonance, not the phase shift in a length of line versus frequency. What happens if you take your phase readings at several points across a range of frequencies, say 100MHz to 250MHz? What happens if you set up like in your first "calibration" phase, with the two probes at the outer ends of the two 75 ohms sections, and then compare between putting the 50 ohm load on (say) the B channel, and then putting the 50 ohm line section between the BNC T and the load? Things shouldn't change, doing that. And finally, what is the impdeance looking into the probe?

The stubs represented by the BNC Ts will cause some loading, but I don't think you could account for 30 degrees that way.

Do you have an independent way to check the phase accuracy of your meter? Like, a 10 ohm resistor across a probe, and a small capacitance--4.7pF, 10pF or so--from the generator [monitored by the other probe] to the 10 ohm. That should give you a known phase shift close to 90 degrees, if you know the capacitance reasonably accurately. You should be able to know it quite a bit closer than 30 degrees anyway.

Someone else mentioned taking velocity factor into account, but if you had measured off half a meter of line, the velocity factor would give you MORE phase shift, not less.

Cheers,
Tom

The antenna you pick should depend on just what you are trying to receive. Could you give us any more info?

As for digitizing the signal, yes, you can actually buy receivers with digital output, though good ones tend to be expensive. If you want very broadband digitization, you can get ADCs that sample at 10^9 samples/second and above, but only to about 8 bits of resolution, and accuracy even less than that. If you want to digitize only a relatively narrow band, you can use analog techniques to convert the signal to a lower frequency, or you can use an ADC that is capable of "undersampling" -- accurately sampling a signal at a frequency above half its sampling frequency. In either case, you need filters to insure that the band of frequencies you let through doesn't cause "aliasing". (You should be able to find plenty on that with a web search.) Anyway, there are some key questions: what signals do you want to receive, and what bandwidth do you want to digitize? Do you want to be able to adjust the center frequency of the band you digitize, or will it be fixed? What dynamic range do you need? What amount of noise in the receiver can you tolerate? Without answers to these basic questions and some others, you probably won't get the results you seek. On the back end, another question is, what will you do with the data? Can you record it or process it real-time without choking on it? And finally, are you looking to buy a system, or build one, or some combination?

Cheers,
Tom

You don't need to go to anywhere near that much trouble. If you replace the stinger with a lumped series RC to ground with the same impedance as the stinger, you'll get nearly the same currents, both magnitude and phase, at the top and bottom of the coil as you did with the stinger. No "missing degrees" -- no "degrees" at all, in fact. No forward and reverse traveling waves, no standing waves. No smoke and mirrors, no bafflegab. Just plain old circuit analysis.

Forgive me for asking questions about seemingly obvious things, but something isn't as it appears. If it's really like you've described, the phase difference should be 90 degrees.

Please verify that the added 50 ohm quarter wave section is between the end of the 75 ohm line and the 50 ohm terminator/probe connector as you described and not between the signal generator tee and one of the 75 ohm lines. If the latter, you will get something other than 90 degrees of phase shift, although I haven't run the numbers to see what it would be.

Are you sure the added quarter wave line is 50 and not 75 ohms?

Also, what's the ratio of voltage magnitudes at the two probes?

The Buxcomm baluns seem to mention "THE core" when describing their 4:1 "current" baluns, and I've had plenty of my responses to my question of whether or not you can wind a true 4:1 current balun on a single toroid core.

The answer is no.

I'm sure if you go with the Buxcomm "BIG TALKER" "2500 watt" unit it won't overheat. It won't ensure equal currents either.

On a marginally related note, why buy when you can build? Better, easier, and probably cheaper?

Better? Nope, not a real current balun and good luck getting real technical info out of many vendors.

Easier? Yeah, unless you have to spend months trying to figure out why, even though you've got a "current" balun keeping the common mode RF "off" of your feedline, you still get RF bites from your mic.

Probably cheaper? Very possibly true... it is often cheaper to buy an assembled product than to buy the parts and put one together, but that's just no fun!

I can't advocate the purchase of simple ham radio station accessories when someone is trying to build them instead.

Howdy:
When a 1/2 wave vertical is about 1/2 wave off the ground you get your best radiation pattern without extra lobes, but
if you were to put it on a tower, several wavelengths high, you get multiple lobes. My question is how can you
keep a clean radiation pattern when you are several wavelengths high with a 1/2 wave antenna? Can you put a ground
plane 1/2 wave below the antenna to keep the clean pattern?

Date: 2006-05-03 22:15:28 UTC
From: Gary Schafer <gaschafer@comcast.net>
Message-ID: <5dai52dp1ftujkssdqjh8398q2l5gusemr@4ax.com>
Source record: 60155

Thanks guys for the replies.

Yes the 50 ohm line is between the 75 ohm line and the bnc/ probe connection.

I did try the 50 ohm line between the bnc T and the load as K7ITM suggested. No change in phase.

These lines are factory made, cushcraft, lines and connectors. The 75 ohm sections are RG59 and the 50 ohm section is RG58/U. The connectors are crimp on PL type. The barrels are PL type.

My additional adaptors are 1 PL type barrel, a PL male to bnc female adaptor and the bnc T at the ends of each side where the 50 ohm loads and probe connections are.
The rest of the PL barrel (between the 50 and 75 ohm line) and PL type T connector at the generator is factory supplied as part of the network. I added a PL female to bnc male at the PL T to connect to the generator.

The length of the 50 ohm line is 9 ï¿½" from shielded area to shielded area (not counting the center pin exposed when shell is pulled back). With the barrel installed it makes it 10 ï¿½" in length that is shielded.

The two 75 ohm line sections from the center of the T connector to the shielded part of the connector on the other end are 10 ï¿½" for each.

The following are readings on the 8405A: 50 ohm line is installed in the B channel side. (with both 75 ohms lines installed as described)

180 Mhz = -90 degrees A channel -5dbm B channel -2dbm.
145 Mhz = -60 degrees A channel -3.5dbm B channel -3dbm

The following sweep was done:
110 Mhz = -55 Degrees.
160 Mhz = -65.
170 Mhz = -80.
180 Mhz = -90.

The following was measured with an MFJ 259B in place of the signal generator at the input T:
Freq SWR R X.
110 1.0 46 2.
120 1.0 46 0.
130 1.1 44 3.
140 1.2 41 7.

145 1.3 39 8.
175 1.5 33 7.

As far as verifying the 8405 at 90 degrees it seems to give the 90 degree reading with the 50 ohm coax length by itself with the method I earlier described with the two attenuators and T connector at the generator.

Reversing the probes gives the same reading but of course the opposite phase.

My thought is that the extra Barrel, Pl to bnc adaptor and bnc connector add enough length to change the impedance enough to throw things off? But the longer length seems like it would give more phase shift rather than less?

I think th probes are supposed to be around 100K? load. I also have some isolators for the probes which I tried and still got about the same readings. They raise the impedance of the probe. Not sure by how much offhand.

With the 50 ohm line and one barrel connected by itself to the MFJ259 it seems to dip at around 145 Mhz.

Thanks for the help.

Gary K4FMX

Here's an interesting quote from S.A. Schelkunoff, "Theory of Antennas of Arbitrary Size and Shape", Proc. of the I.R.E., September, 1941 (footnote 17): "From the point of view developed in this paper there is no difference between 'end effect' and radiation."

This is the paper in which Schelkunoff develops his often-quoted approximate equations for antenna feedpoint impedance (the ones including sine and cosine integral -- Si and Ci -- terms). He says, basically, that an antenna acts like a transmission line -- a conical antenna like a constant-Z line and a cylindrical (e.g., wire or tubing) antenna like a variable-Z line -- *except at the ends*. At the ends, modes other than TEM are excited, resulting in radiation, modification of antenna impedance, and modification of current distribution. The radiation, he says, can be modeled as either a terminating impedance or as a distributed impedance (R and L) along the line. You can find an abbreviated version of this explanation in Kraus' _Antennas_.

A transmission line is similar to an antenna in only some respects, and assuming they act exactly the same leads to erroneous conclusions. Among the many mistakes made in recent postings is the assumption that a complete reflection takes place from the end of an antenna wire. As Schelkunoff, Kraus, and others explain, this isn't correct.

You would have to create a ground plane that extends many wavelengths from your antenna. The multiple lobe pattern is produced by reflections from the ground which are far away -- the lower the angle, the farther from the antenna.

Why don't you just lower the antenna to 1/2 wavelength if that's the pattern you want? Then you'll have just the ground plane you need, the right height below the antenna -- the ground.

Otherwise expressed as a finite Z instead of a zero current (infinite
Z) point at the end. Of course, finite and infinite are relative even
for Schelkunoff.

>The
>radiation, he says, can be modeled as either a terminating impedance or

Hi All,

Pretty much what I've offered in the past and recently in this thread
(same source, Schelkunoff through Robert Collin). Anyway, I see no
formulas offered and as I don't have Kraus to see if they are missing
there too:
Zc = Z0 ï¿½ ln (cot (theta/2)) / pi
for
Z0 = 377 Ohms
theta > 5ï¿½
or
Zc = Z0 ï¿½ (ln(2) - ln(theta))) / pi
for
theta < 5ï¿½
where theta is the half angle of the cone section.

This, of course, says nothing of the variable Zc for a thick radiator
(which is not conical, but cylindrical). The "average" Zc:
Zc = 120 ï¿½ (ln (l/a) - 1)
for
l: length
a: diameter

The Zc as a function of position:
Zc(z) = 120 ln (2 ï¿½ z / a)

How can you arrange 16 receivers with an homebrew antenna system? I'd like to have three antennas or no more than four ideally. I'm not interested in direction finding, need low profile for neighborhood, and to work in the space uhf/vhf frequency range.

Is it really necessary to do much more than hook up the wires, or must they be electrically isolated somehow and therefore need a fancy design?

If it is easier than drawing diagrams, can you otherwise recommend a low profile space/sat antenna system that might function well with multiple receivers?

> month discussion.
>

Dave,
your 8 ft mobile antenna is not 90 degrees long, you don't have zero reactance at the feedpoint. You will have to insert the loading coil or matching network to do that and that adds the missing degrees. (You might have maximum current as far as the whip is concerned, but not maximum current corresponding to the base of resonated whip, just fraction corresponding what standing wave would supply for that tip o'antenna.)
Then you have drop of current along the coil, (missing degrees) and rest in the stinger at corresponding degreed to the straight radiator. (Worst efficiency of that length of antenna.).
As you start moving the loading coil up the antenna, you start increasing the high current in bottom part of antenna, then drop along the coil, then rest of the drop towards the stinger, down to zero. As you move coil higher, you will have to add the turns in order to maintain resonance (90 degrees overall, zero reactance at the feedpoint).
Looks like my idea about the role of impedance has some merit, Cecil is hitting it with idea of "losing" some degrees at the impedance "bumps" completing the picture of them mysteriously missing degrees, to dismay of same current believers. So looks like degrees of mast, plus degrees of impedance bump between the mast and coil, plus degrees of coil, plus degrees of impedance bump between the coil and stinger, plus degrees of stinger should add up to 90 degrees in resonant monopole or resonator, as some antenna pioneers called it. Do we get it now more precisely? Or there are still some "missing" degrees floating around?

All,

What is the best way to base impedance measurements, by voltage and current phase or by forward and reflected power?

First I assume both methods provide the data to measure impedance.

It would seem that both suffer from the real effects of the taking the measurement. Measuring voltage suffers from the effects of the reflected signal, I would assume current does as well. Couplers have a built in cross talk parameter.

Thanks,

- Dan

> current phase or by forward and reflected power?

Measurement or calculation of forward and reverse power don't give you enough information to determine impedance. There are an infinite number of impedances which result in any given set of forward and reverse powers.

Likewise, voltage and current phase don't provide enough information. Again, there are an infinite number of impedances possible for any set of voltage and current phases.

> First I assume both methods provide the data to measure impedance.

No, neither one does. Among adequate sets of measurements which will allow you to determine impedance are both magnitude and phase of both voltage and current; or the ratio of voltage and current and the difference between their phase angles; or the magnitude and angle of the reflection coefficient.

> It would seem that both suffer from the real effects of the taking the

> signal, I would assume current does as well. Couplers have a built in
> cross talk parameter.

It's much more difficult than most people realize to make accurate RF measurements. Any measurements have numerous potential sources of error. If you need accurate results, you should always measure a number of known impedances approximately equal to the measurement being questioned to verify that the system is sound. Measuring antennas brings the additional problems of coupling among the antenna, test equipment, and you; disturbances from other signals being received by the antenna; common mode currents; and properties of connecting feedlines.

> . . .

By my reckoning, a free space quarter wavelength at 145 MHz is 20.335 inches. Assuming solid polyethylene dielectric coax, this would be about 13.4 inches of coax. 10-3/4 inches would be about 72 degrees.

The probes have a shunt C of 2.5 pF, resulting in a Z (-X) of about 440 ohms at 145 MHz, not 100k ohms. If you parallel that with 50 ohms and terminate a 72 degree 50 ohm cable with it, the voltage delay in the cable is 78 degrees -- that is, the imperfect termination actually increases the cable delay by 6 degrees. If the cable Z0 is 45 ohms instead of 50, the delay is a couple of degrees less with that load; if it's 55 ohms, the delay is a couple of degrees more. Maybe your 50 ohm termination isn't quite what you think it is -- as you can see, it doesn't take much to substantially change the cable's delay.

As I've said often, most people don't realize how difficult it is to make accurate RF measurements.

Myself, I wouldn't worry about the pattern too much.
The higher antenna will still beat the lower one in most
cases despite the extra lobes at higher angles.
Of course, where you are talking will make a difference too.
But you do think a 1/2 wave at 4 waves up will lose to a
1/2 wave at a halfwave up to a ground/space wave contact 30 miles
away? "10 m as an example" Better think again...
The higher antenna will likely eat the lower one for lunch.
And we are talking pretty low angles involved.
Also, on the HF bands like 20m, a higher vertical will often "open
and close" the band earlier and later than the low antenna
when talking long haul dx. But not much difference on
medium or short paths. Yes, there are often higher angle
lobes involved on real high verticals, but if you think that
ruins them, you will be in for a surprise. If I were on 10m,
and had my pick of a 1/2 wave at 25 ft, or a 1/2 wave at
120 ft, I'd take the taller one any day of the week.
I wouldn't let knowledge of theory ruin a good thing. :/

If in a transmission line where the Z0 is known, either method
will give valid results within a certain accuracy. A bridge
circuit would probably yield the most accurate measurement.

Roy,

Thank you. Yes, I understood both magnitude and phase are required for both.

The question arose after looking into the block diagram of an HP 4805a Impedance Meter. It measures voltage and current as the basis for determining impedance.

My work with a vector voltmeter has been through using directional couplers and measuring forward and reflected power.

My question is: Is there an inherent accuracy benefit to one measurement basis over the other?

Or: Are current and voltage probes inherently easier to build and more accurate then directional couplers?

- Dan

It is also important to check the terms of your license. In the U.S. 2.4gHz is shared between amateur (Ham), ISM (industrial, scientific and medical) and unlicensed users. Each has it's own terms and conditions.

For example, the infamous Pringles can antenna was designed and used by an FBI agent in the course of an investigation. It may not have been legal for use by regular unlicensed WiFi users.

This is a health physics project. Everything is pointed up at one end
and a data logger at the other end. Basically everyday it just takes a
reading, or space weather ob, and I'm just a hobbyist more familiar with
the data logger and where to find local health stats. I guess it just
points up and has to keep track of space weather for the next forty
years. Any suggestions or links to or from real health physicists
would be wildly appreciated.

There is an Agilent app note about this... The short answer is: near z0 of your couplers, (50 ohms) use a network analyzer, at high or low impedances, use voltage and current.

Kinda hard to do if the feedline is ladder-line. Maybe a more
logical thing to do is to increase the length of the ladder-line until
a current maximum point is available at the coax/ladder-line
junction.

Hi Dan,

Probes have the benefit of being more sensitive, but you pay a price
in a far greater probablity of distorting the measurement. Unless, of
course, you are only looking for an indication which is qualitative
instead of quantitative.

Directional couplers are quite robust, accurate, and in my experience
I've never seen one that fell outside of its tolerance - except at the
band edges.

What they seem to be saying is that a quarter-wave monopole
could be modeled like this:

======1/4WL 600 ohm line======12K load

The 12K load dissipates approximately the same amount
of power radiated by a 1/4WL monopole so the conditions
at the feedpoint will be similar to the 1/4WL monopole.

Just because it can be modeled in that fashion doesn't mean
that the radiation is from the same place as the 12k load.

This does seem to be a good way to understand the forward
and reflected waves occurring in a 1/4WL monopole. Guess
what the feedpoint impedance is?

Another way to model the antenna would be with resistance
wire instead of transmission line wire. Then we wouldn't need
the 12K load resistor. We could just specify 1 dB loss between
the forward power and reflected power.

Thanks for the clarification.

The HP4805a isn't an impedance meter. It's a vector voltmeter, which measures voltage amplitude and phase. As you know, it requires external directional couplers to measure impedance. (Or you could use current measurements using current probes in addition to the voltage measurements.)

When you use directional couplers with the vector voltmeter -- or with a network analyzer for that matter -- you're not measuring forward and reflected power. You're measuring forward and reflected voltage. As I mentioned in my last posting, power measurement doesn't give you enough information to determine impedance.

The answer to your question is that you can't measure impedance at all using only the voltage probes of the 4805a, and you can't measure it at all by measuring forward and reverse power with directional couplers. If you want to compare using voltage *and current* probes with measuring forward and reverse *voltages* with directional couplers, the former is probably better when impedances are considerably different than 50 ohms resistive, the latter better in a near 50 ohm system. Making accurate measurements with either method is much more difficult than most people realize, and it helps to have an understanding of what you're actually measuring. Both methods have numerous sources of possible error which have to be understood and controlled.

I have no idea how your second post in this thread relates to your first one, but...

If you want any sort of sensitivity for 16 receivers tied to the same antenna, especially in the UHF range (where even with a single receiver, the receiver noise is likely going to dominate over the noise the antenna picks up), you should put a decent preamp on the antenna. The power from the antenna, best case, will divide among the receivers. In the real world, you'll loose some additional power in the system you use to split the power among the receivers. Just tying them all together is about worst case. It would be reasonable to look for a preamp with perhaps 15dB gain, and in fact you could find a distribution preamp that will divide the signal for you and give you more-or-less isolated outputs. One way they do it is to have an input amplifier, say a 4-way splitter, and then another amplifier on each of those splitter outputs, each of those driving another 4-way splitter. That generally gives better performance with respect to distortion and noise.

If you're only dealing with large signals, you could try just a simple splitter arrangement, but don't expect good sensitivity in the recievers.

Cheers,
Tom

I'm going to take slight issue with what Roy wrote about measurement using a directional coupler. Though it's true that the receivers could be considered to be measuring voltage, they are measuring it across a well known load (very close to 50 ohms). When we set up a system to test the performance of units we build, it's done very carefully to calibrate them for input _power_, not voltage. The usual directional coupler in a VNA is indeed a resistive bridge, with some care taken to make the known legs and the source driving it and the load observing the imbalance all 50 ohms (in a 50 ohm system). Generally a bridge whose impedance is near the impedance you want to measure is a good choice for a starting point for making accurate measurements, but it's for sure not easy to build a 10k ohm bridge at 10GHz, for example...

I certainly agree with Roy that an understanding of the measurement system and the error sources is critical to getting consistently good measurements. In fact, I have several old ap notes from HP about such measurements; those ap notes may still be available through the Agilent web site, but I couldn't guarantee it. NIST (the US National Institute of Standards and Technology) has done a lot of work in characterizing errors in measurement, and they are also a source of good (but usually mathematically deeper) info. Rohde und Schwarz is another source of VNA and impedance measurement ap notes. It's such a complex subject that I really wouldn't want to even try to get into it here. And why, since it's already been dealt with nicely in freely available pubs?

Cheers,
Tom

1956. Re: spectral power density

Source record: 59945

If your modulation spreads the power evenly over 500kHz, if I understand the rules right, you can transmit 1 watt. If your modulation spreads the power evenly over 50kHz, you could transmit 0.1 watts (+20dBm). If your modulation spreads the power evenly over 5kHz, you could transmit 0.01 watts (+10dBm). It _appears_ that you could transmit +8dBm (6.something milliwatts) however you want in that band: as an unmodulated carrier, or spread however you want. I don't suppose they talk about the time period over which you measure the spectral power density...but they probably wouldn't like it if you transmitte 1 watt that swept linearly and slowly across the 500kHz, say once a minute. Over a long enough period, that would be uniform power per unit bandwidth, but a one second snapshot would show 1 watt in 500kHz/60 = 8.3kHz bandwidth.

Hope that makes sense. Beyond that--see your lawyer! ;-)

Cheers,
Tom

I gladly defer to Tom, who has a great deal more experience with and knowledge of measurement devices and techniques than I. My point was that you need to know magnitude and phase of the measured quantity if you're going to determine impedance. If all you were measuring was power, you wouldn't have this information. So you must measure the voltage (or current).

Where I am at, we get some pretty strong and gusty winds the past few
years. The trees can get whipping in different directions fairly often.
My old nylon string would stretch, and could even
support my weight (don't ask how I know that) My thoughts are that iff I
put up something that doesn't have a little give, the stress is just
going to transfer from the line to the antenna. At that point I'd start
breaking the antenna.

Nothing so complex. I have some line running through a grook in the
limbs. The failure point for the old stuff I was using was at the rub
point. Now it seems almost random. Your method would probably be a lot
better for me to use.

Once again, sounds like a setup I might want to emulate.

Thanks, Dave.

Whoa, hold on, wait a minute or as we are now required to say in
Southern Arizona, Alto Amigo!

I think that Dan made a typo and meant to say "HP-8415", which is a
vector impedance meter that does use a constant current r-f source and
a voltage measurement to determine impedance.

It's a handy instrument for probing circuits, but it has a limited
higher frequency limit of 108 MHz.

There is one here:

http://cgi.ebay.com/HP-4815A-RF-VECTOR-IMPEDANCE-METER-500KHZ-TO-108MHZ_W0QQitemZ7609873605QQcategoryZ25421QQcmdZViewItem

but without the probe, which makes it totally useless.

First of all thanks for your answer.

K7ITM wrote:
> The antenna you pick should depend on just what you are trying to
> receive. Could you give us any more info?

I have to be able to read an UHF signal produced by an ISO-18000/6 (not B version) RFID reader/tag signal. I first thought to directly use the tag's antenna itself but have no idea of how to connect it to a sampler. Plus it uses backscatter asa means of communication and don't know how this influences any signal at the end of the antenna.

> As for digitizing the signal, yes, you can actually buy receivers with
> digital output, though good ones tend to be expensive.

Well, we are a research lab. Sooner or later I think we'll get our hands on something if it's actually usefull and we ask for it. Nevertheless it has to be as cheap as suitable.
--Inline Edit--: I have to ask our providers if they have any passive reader they won't miss ;-) .

> insure that the band of frequencies you let through doesn't cause
> "aliasing".
> (You should be able to find plenty on that with a web search.)
Thanks, I'll go and search as I don't remember very well. The band is as narrow as 70MHz if I'm not mistaking. Take a look at

http://zone.ni.com/devzone/conceptd.nsf/webmain/1622E8ED427AA28C8625714D0067926D

As I told you I'm a total noob and I don't even know if there's only a channel or more (though I think there's only 1)

> Anyway, there are some key questions: what signals do you
> want to receive, and what bandwidth do you want to digitize?

Well, there are lots of RFID protocols out there, but as this is our first test I think we should do simple things. That's why I chose this protocol (it should be simple (yet very complicated for me!) compared to the ISO 18000/6B).Do you think this should be easier in HF (125/130kHz) or VHF

(13.56MHz) domain (we have any kind of readers:-).

> Do you
> want to be able to adjust the center frequency of the band you
> digitize, or will it be fixed? What dynamic range do you need? What
> amount of noise in the receiver can you tolerate?

I'm not really a guru of telecom. The only thing I can say is that the S/N ratio is *probably* no problem to me ... just get the reciever closer to the emitter and I *think* it would be ok. Correct me if I say any nonsense.

> Without answers to
> these basic questions and some others, you probably won't get the
> results you seek. On the back end, another question is, what will you
> do with the data? Can you record it or process it real-time without
> choking on it?

No real-time processing. At least for now and a good deal of time from now. I first have to understand how this works. Plus once it's sampled I can do all the tests I need to.

> And finally, are you looking to buy a system, or build
> one, or some combination?

It depends on how much time would cost (or how much money...).

Cheers and thanks again,
Alexander

Hi Roy:
With 10 meters and above, the higher you have your antenna, the better
the local reception. I like to get above the power lines.

Remember you are using wavelengths as your measurement. On 160-meters
6-foot separation would be okay.

It must have been something in the way that Roy worded it the first time, but with that concise rewording, I absolutely agree! You gotta measure phase as well as amplitude if you want to determine a complex impedance. In no way should my previous post in this thread be interpreted as going against that.

Cheers,
Tom

>Roy Lewallen, W7EL

Measuring RF is difficult! I can't seem to get any two methods to come
out in the same ball park.

If I just have the two 75 ohm lines hooked up with 50 ohm terminations
on the ends and measure with the probes I get 0 degrees phase.

I can hook one of the 75 ohm lines only with a 100 ohm load and one
probe at the generator end and a 50 ohm load at the other end with a
probe and see near 90 degrees.

I can do the same with the 50 ohm line with a 50 ohm load on each end
and see near 90 degrees.

But when I have the two 75 ohm lines and add the 50 ohm line in one
leg I get only around 60 degrees. By pulling the probe of the
connector (B channel) at the end of the 50 ohm line, and keeping the

center pin close but not in contact so there is only light capacitive coupling the phase shift increases by around 10 degrees or so.

If I add a few elbow adaptors to the 50 ohm line to increase its length to arund14 ï¿½" inches or so then I see close to 90 degrees.

So it would seem that my 50 ohm line is too short but when measuring it without the 75 ohm lines it looks to be the right length.

I built a couple of different 90 degree phasing setups several years ago using two 75 ohm ï¿½ wave length lines, a spdt relay and a 90 ohm ï¿½ wave length line all hooked to the relay to be able to reverse polarization.
I measured that setup in a similar manor only the center of the relay went to the signal generator and the 50 ohm loads and probes went at the ends of the 75 ohm lines. I get 60 degrees of phase shift on that setup too.

I don't remember how I trimmed the 90 ohm line at the time but I do remember I tried several different methods to try and measure what was happening and had the same problems I am having now. I didn't have the 8405A then.
It seems I am doing no better with it. :>)

I would like to find a repeatable method that will work when adding a relay and or connectors to be able to know pretty close what the actual delay is.

Thanks for the help.

Thanks Tom,

I do have almost as many splitters and amps as receivers. You call them scanner receivers, but since some of them are computer controlled, they ultimately are good for all kinds of natural sampling experiments. So as you suggest, I'll start with the most simple arrangement and work backward until the receivers start to work well per experiment. I have done electronics, device, and ac/dc circuit analysis before, but nothing in radio frequency space. I knew there was a plan! Thanks Tom.

I worked with nws/asos equipment once and so want to build a hobby "instrument" that could record anything, space weather wise, in the radio frequency realm, that might -or not- wash over the city and trigger health problems. It would systematically record as "large a signal" then as regular weather observations detect with traditional instruments and from a fixed position.

A big smile,
notyeti

> multiple receivers?

Yes, they absolutely must be isolated or you upset the impedance of the system. Isolation is done with splitters or directional coupler taps. T-connectors are often a problem, as they tend to encourage reflections in the cables.

I presume that you have a low-noise amp at the antenna that sets the noise figure for the system. Thus, all you have is a divider problem and many, many amplifier/splitters that are flat from 50 - 1000 MHz are available for home and small apartment TV systems. If you need to get into L-band, there are booster amps for SAT-TV that do well from 950-2250 MHz.

I googled for 8 way splitter amplifier low noise TV and got this among the thousands:

http://www.smarthome.com/7750-8.html

not saying it's the best ... it's just one of the many.

Good luck.

I should be able to keep this from getting to me, but sometimes I just feel like responding to the attempted intimidation by these elitists.

Mate, your key is only silent from the neck, up.

Due to dyslexia, I am unable to learn much Morse Code. I can consistently recognize about half of the alphabet and none of the numbers. Morse Code might as well be edoC esroM for all the good it will ever do me.

In spite of this, I manage to be a responsible member of the ham radio community and I'm damn proud of my service to RACES, to my club as its treasurer and to the county as a volunteer communicator. My UHF/VHF points in last year's Field Day exceeded the points of our HF stations combined. Lower life form, indeed! The nerve of you!

You may get down off your high horse (or should it be "High Morse"?) and apologize for all those jabs any old time it pleases you. I'll be here.

I got a seat on the train going both ways on Monday -- quite a rarity.
They can take the whole month off.

Heard a good one on Monday: The illegals telling us to revise our laws is
like a burglar telling you to rearrange your furniture.

1975. Re: RF/microwaves over Fiberoptic cable???

Howdy!

A few comments on fiber:

1 - we cannot confuse bandwidth (MHz) with bitrate (Mbps or Gbps). Two different monsters. Currently CATV uses fiber optics to transmit TV signals over RF, also called analogue video. You will need, of course, a transceiver on both ends, which will be powered by electricity that will then "power" an antenna. That would be an awesome solution (if economically feasible for HAMs) in places with lots of lightning storms (e.g. Florida). If a lightning hits an antenna the only things fried would be the antenna itself and the transceiver. Since fiber is dielectric (assuming the use of an all-dielectric cable also) the radio would be fine if not surge came through the power line. Fiber optics can have (depending on the type) TeraHertz in terms of bandwidth and transmit TeraBits of information per second using techniques such as Dense Wavelength Division Multiplexing, which is simply sending multiple colors (or wavelengths) through it.

2 - tapping into fiber. Not so easy as mentioned above. Transmitters can be equipped with optical power variation detection and the system themselves can also detect variation in the BER (bit error rate) that would raise if someone tries to tap into fiber. Those two controls make fiber virtually impossible to undetected tapping. "Shaving" fiber by eroding its coating will only make the intrusion even more noticeable since there will be a big optical power loss in a certain point of the link. That point can be precisely detected within a few feet range by using an OTDR (optical time domain reflectometer) that can locate the failure in seconds and, depending on security level of the link, let the security personell take "appropriate care" of the "spy". So, do not try this at home.

It is easier to hack into someone's network via computer code than via the optical physical medium.

Cheers!

Here's one that I haven't even seen:

Not everyone speaks readable English, but anyone that knows Morse can copy
any language and read it at their leisure. Also, those who don't speak
English well can often spell the words well enough to read...

Just a thought.

In order to graduate school in the Navy we had to both read a punched
teletype tape and read morse code. I don't recall how fast the code was
but the test day was a bitch!

Mis-statements abound again.

Read the allocation chart in 47 CFR 97.305(a) and 47 CFR 97.305(c). What
CW sub-bands?

47 CFR 395(a) "An amateur station may transmit a CW emission on ANY
frequency authorized to the control operator." [EMPHASIS ADDED]

For USA Amateurs CW is authorized as stated above.

If you really believe that morse code is an important way to communicate that should be preserved then you need to convince other hams and potential hams to learn the code. You need to convince enough hams to use code so its very usage generates excitement and makes people want to join in the fun. Almost self-perpetuating like it was in the 1950's.

Preaching (or complaining) to the choir on the radio fora about the abysmal state of things will not add one person to the ranks of key pounding hams.

So what are you going to do to increase the number of code practicing hams.

Please all, remember,

The common-mode currents the choke is suppressing are not necessarily related to the antenna impedance (the load) or the transmit/receive currents flowing in the antenna, though there can and will be some coupling between the two on an antenna (if you measure antenna Z with/without a choke they will usually differ).

To place the choke in the best spot, you need to measure the common mode current on the feedline and not the load impedance. If you have common mode currents induced by an unbalanced situation in the antenna itself, right at the antenna is probably best. Other places might be good if you are coupling electrical noise to your feedline.
W1HIS's article was most interesting in this respect.

I would assume that because the feedline current is common-mode (the same in both conductors), it will usually travel at the velocity factor of a wire in air rather than the feedline velocity factor, though I do not know this.

CW will not be lost in the same way that AM is not lost.
A lot of hams in the 1950's believed that SSB would cause
the death of AM and ham radio along with it. SSB operators
sounded like Micky Mouse and were known as Single Sidewinders,
undesirable snakes in the grass within the hobby, and traitors
to the traditional form of amateur radio AM communications.

Seems like a reasonable assumption given skin effect and the
outside braid of the coax. Common-mode current also, no doubt,
forms standing waves with current minimums and maximums 1/4WL
apart. A choke would be most effective at a standing wave
common mode current maximum point.

If you are in the US you do not need to look at any diagrams. Just get a
book that has the question and answers in it. Then memorise it. They are
the exect question and answers.
That will put you to the Tech license and the code may soon not be needed
for the low bands.

Well, "SC" a.k.a. troll,

Cw, when it came along, was frowned uopn and was predicted to be the death of ham radio as well. Did you know that?

Modes currently around that full knowledge of is NOT required to get a licence (where complete knowledge of sending and receiving all the characters in Morse is a requirement):
AM, SSB, RTTY, PSK, Paclet, Amtor, APRS, satellite...basically everything else in Amateur Radio!

I said *full* knowledge. Do any of the tests require explanations of all five (or is it ten) methods (circuit types and how they function) of generating SSB or how to generate CW...or proper operating practice in all situations?

Do you know WHY knowledge of Morse was required in the first place?

I think there should be more on the tests on operating practices. I know some Techs who can do much of the above and make better hams that any old fart crying over the supposed loss of CW. I know Extras who couldn't copy code worth a darn, nor do much in the way of tech stuff...so? They're all friends.

Your fingers and eyes (or ears) aren't broke... so why aren't you out mentoring new hams? In the last two years, how many programs have you written for helping hams with things like blind hams controlling rigs or or audio tapes on radio operation have you recorded for blind hams or trips to help a blind ham erect an antenna, do a small project or program his radio or cables you've given to a new ham for his antenna or taken a blind ham to a hamfest... Why am *I* wasting my time with this...pfffvt

I'll save you the trouble, I'm a 60 year old, 20 WPM Extra and currently spend most of my ham time on 2 & 440 from the car during drive time on repeaters (much more omitted)!

I didn't have to learn code in the Navy (though I did happen to already know it)

Jerks are everywhere and I wonder why I wasted this time. Guess I just needed a little vent...sorry folks..time for lunch.
73, Steve, K9DCI

Answers to the above questions for me: 5, 4,0,1,10,3,1 - not astounding, nor bragging, just true.

We were somewhere around Barstow, on the edge of the desert, when the drugs began to take hold. I remember Silent Key <cw.h@m.bands> saying something like:

>When CW is lost, new hams will be just like CB'ers and SWL's, or some
>other lower life form of radio hobbiest. You name it.

Go back to playing with the dinosaurs.

Yep! I stand corrected!!
5330.5 KHz USB ONLY, Maximum band width 2.8 KHz. 50 watts ERPd max.
5346.5 KHz USB ONLY, Maximum band width 2.8 KHz. 50 watts ERPd max.
5366.5 KHz USB ONLY, Maximum band width 2.8 KHz. 50 watts ERPd max.
5371.5 KHz USB ONLY, Maximum band width 2.8 KHz. 50 watts ERPd max.
5403.5 KHz USB ONLY, Maximum band width 2.8 KHz. 50 watts ERPd max.

And, "I dare not call it a 'band'" either. Just 5 channels occupied by
gentle men and gentle women, both genders, with manners.

I have three rigs that operate '60' meters. I've gotten to love that
non-band.

/S/ DD W1MCE

That's what I did, 10nF added to the loop- var cap setup, and now I see that RMC INfo on 216 comes in with sig 9... (without loop: about 1).

Strange thing is that with var cap + 10nF the loop only tunes between say 207 and 225 khz, while on AM (without the 10nF), it tunes 1 MHz wide ..

explanation ??
I saw that some people make their own var cap ... (with very large plates...)

Now, I intend to buy some nF caps from 1-50nF or so, to see what's happening ...

Today I picked up two old grundigs, and after some tweaking (knobs) they work !
melody boy 500 (excellent condition, the AM-FM- etc knobs aren't touched ...)
and a Yacht boy with lamp, batt indication, AFC ... tunes very well on SW...
Great sound on both radios ...

---and now, for a great song: ---

----
You're just an antenna, you're just a wire.
There's a thousand tongues wagging in your ears tonight,
And you turn around and you call me a liar.
Lightly babe, oh the fine lights cannot find you.
She stay out my way, it's the pulse I am aligned to.
And everything you say, you'll need that breath one day.
Well, you're just an antenna, you're just a code.
You translate like a book, the fuses all cook.
You eat humble pie and it tastes of the road.
Lightly babe, oh the fine lights cannot find you.
She say, that's the way, that's the fate I am resigned to.
And everything you say, you'll need that breath one day.
You're just an antenna, you're just a gauge.
You disturb my slumber and round up the numbers
And put them inside your velvety cage.
Lightly babe, oh the fine lights cannot find you.
She say, make my day, and the sunlight will not blind you.
Lightly babe, oh the fine lights cannot find you.
I may never pray to the fortune that's behind you.

Your variable capacitor (probably in the 20 to 400pF range) is a small
percentage of the total capacitance when the 10nF is added to it.
Alone, and at a higher frequency, it is enough to cover that much
range.

Oh what a sunny day
When they carried the radio home
Bringing him in off of the truck
And the dogs wouldn't leave us alone
Mr. Radio
Come down here to keep us company

We listen in a room
Through the miles and miles of night
Deep in the heart of the Bible Belt
In the golden radio light
Mr. Radio
Come down here to keep us company

And it's hard days out in the field
The crows in the high tree top
If the man's away from his home all day
His chickens might fall to the fox
Mr. Radio
What can you do about that uh huh

And you can take me down to a river town
Where the citizens dance till dawn
Dance so close it's a sin almost
The way they carry on
Mr. Radio
I never dreamed you could

And it's miles at the careless touch
Of a tired hand in time
When evening fell I heard a stranger sell
Dreams that were never mine
Mr. Radio
Come down here to keep us company
Come down here to keep us company

I'm fearing it will be Eminent Domain ham radio style.

They'll see spectrum that they don't have the ability to use, because there will be no requirement to have that ability. They will want the spectrum for phone. One good thing, there are other modes besides CW that need it, so maybe they won't take our CW portions and give it to phone only hams and appliance operators.

Thank you.

In a way, it's sort of like sign-language. Two people that don't know
each others tongue but know sign language can still communicate.

Thank you for your service to America. It is people like you that make us
a great country. When hard work was needing to be done and learned you
were there.

Today people are lazy and that's why they want to get a license in as easy
a way as possible, even if it means the service and our ability to
communicate with each other suffers.

Call the FCC, email the ARRL. Tell them you don't want to see ham radio
dumbed down anymore, for the good of the service and the good of country.

God bless America. Amen

But it's the lower qualifications that will cause the service to suffer. I
don't think new general class hams today have as much of a grasp on theory
as new ones did 15 years ago. 15 years ago, they spent more time studying
the theory while they were building their code speed up.

Loss of the requirement to be code proficient though could be offset if
the passing score on written the exams were raised to 85%

Yes, but can you send and receive Code at 13 or 20wpm?

What if in an emergency your microphone broke, and the only thing you had
to save a life was CW? With your skills, that person would die. In that
situation you'd be about as useful as two tin cans and a piece of string.

But we hope that won't happen though.

We already have CB for a codeless service. You want Ham radio to be like
CB?

Right, that's the service nature of hams. Hams helping hams, and hams serving the community. And Dumbing it down can effect the quality of service. Maybe it won't go totally to shit while you and I are still around, but it will happen. In Life, What happens when standards are lowered, things get better?

Actually your own words have proven that you can learn it. You say you can consistently recognize about half the alphabet. So you have demonstrated your ability to learn it.

Perhaps you just haven't spent enough time on it or used a poor training method (there's way too many of those around). Most people's expectations of how long it will take are unrealistically short. For the average person, it will take 1/2 hour per day every day for 60 days.

Now writing it down could be a problem due to dyslexia but there are ways around that. You don't have to write it down. You can ask to be allowed to say the characters into a tape recorder. You could dictate the characters to a VE to write down for you. You could simply jot down notes and answer

the questions and not worry about solid copy. Again if there is a risk of writing it backwards, you could have the VE write down what you tell him/her. Naturally such accomodations have to be set up in advance.

Well, if he does cover 207-225 w/ a fixed 10nF in parallel with whatever tuning cap he has, that implies Cmax/Cmin = (225/207)^2 = 1.18/1. Since Cmin is at least 10nF, the variable to accomplish that must be 1800pF, at least. That in itself is a pretty good size variable cap.

Then the implication would be that L = 50uH, and 1800pF would tune that to 530kHz. The minimum capacitance including stray and effecitve coil shunt would be 175pF to tune to 1700kHz.

I think he means to buy some fixed caps in the range 1-50nF, not a 1-50nF variable. (Though in this forum, maybe he does mean the variable!) The fixed caps could make some sense. Maybe put them on dual stackable banana plugs, and plug together whatever value is desired.

Switcher, you can do the calcs yourself: 2*pi*freq = 1/sqrt(L*C) -- or use something like the RF calculator that's in RFSim99. And you may find it's better to not try to cover too wide a range with one loop by adjusting only the capacitance, for performance reasons in addition to the fact that the tuning range will get very small as you go to larger fixed capacitances.

Cheers,
Tom

< Snip >

Your tuning cap at the low range is only part of the total capacitance
instead of the whole capacitance for the resonant circuit. I have those
duh moments too.

You could use a solid state analog mux IC to switch capacitors at
those frequencies. Maxim, Analog Devices and others make a wide
selection of these chips.

Of course, the same thing is possible on SSB communicating
phonetically.

Well, with the 4 or 5 CW signals that are on most bands at any given
time (except VHF and up during contests, BTW), who would notice the
loss. No offense, but if CW ops want to keep the territory, they'd
better start populating it.

Yup, that increased the number of CW ops by a lot. Typical old style
ham response. Moron. Pure and simple moron.

This is why CW is losing the battle. Not because it's a lost art, or
something that's not worthwhile, but because the "supporters" do nothing
but complain.

I don't want to see CW go away; I think it's a "good thing", and should
stay around, especially for things it still does well, such as EME. Of
course this is not the place to speak of "advanced" things like EME,
after all, it's only been around for 50 years.

Dumb argument.

CW is only being removed as a compulsory exam element. Oddly enough,
now that it is not compulsory, it's popularity is growing!

Which is most likely, actually. We broadcast a lot more voice than CW,
Ever noticed how many watts of television, FM radio and AM radio are
out there versus CW?

CW is effectivly dead except for those that wish to keep it alive.
Similar to the old car collectors. Nothing wrong with it. beautiful
collector items, but not really part of the current world.

Of course, now I can add more turns to the loop.

The loop is 2 x 3 meter of PVC tube, bended in a circle.
There are now 3 turns. Guess ... how many turns to have the LW
153-279khz ???

picture of a previous version , large (2 m) and small 83 cm hulahoop

http://users.fulladsl.be/spb13810/oc/IMAG0015.JPG

The way I construct the hulahoop now, so that it "keeps head up":
http://users.fulladsl.be/spb13810/amloop/loopbottom.jpg
http://users.fulladsl.be/spb13810/amloop/loop83cm.jpg
http://users.fulladsl.be/spb13810/amloop/loopbottom2.jpg
(when the box is closed, you can put a radio on it, nicely positioned
inside the loop)

these formumla's say:
http://www.mindspring.com/~loop_antenna/umr_emc_calc.htm

some 15 turns... on a 2m diam loop ...

I know about the computer flat cable trick...

(I put the first formula in cm (100 cm = 1 meter) on
http://users.fulladsl.be/spb13810/amloop.htm
)

My $0.02: Passing the CW element requires the acquisition of a skill.
Passing the "written" element requires memorizing answers to a test where
the answers are handed out ahead of time. Some accomplishment, eh?

Thank you.

If I may add something to that...
I wouldn't like to see Morse totally disappear, but I'm against its
compulsion for trainees. I fully agree that in some conditions a Morse
tone will get through where voice is an unintelligble mush, if heard at
all, but apart from prisoners tapping out messages on pipes its days as
an *essential* comms tool are pretty much over.

We've all got to move with the times and these days Morse is on a par
with a runner carrying a message in a cleft stick. There will be some
who enjoy using it and I hope they find enough fellow enthusiasts of the
arcane art to keep themselves happy while the rest of us communicate
more naturally.

Don't use the cheap ceramic capacitors that are meant to be used for bypassing. A friend of mine used some in a tuned circuit, and he got a distorted sine wave output. In addition to possibly high ESR, the value of these capacitors changes with the instantaneous applied voltage. To be safe, use caps with mica or plastic dielectric.

CW is just memorizing the sounds . That is not a skill. Yes, I do have the
20 wpm extra. Got up to speed, passed the test, never used it on the air.
I still listen to some about once a month just to see if I can still get any
of the characters.

A skill is more like repairing a piece of equipment or building something.
Maybe even the ability to put together an interisting conversation instead
of the usual WX and Signal reports.

> 153-279khz ???

If 3 turns resonated with about 11000 pF (your 10 nF plus about 1 nF from the tuning capacitor) produces a resonance within that band, then raising the turns to about 9 (3 times as much for about 3^2 times as much inductance) would resonate at the same frequency with about 1/9th as much capacitance (same L*C product). Of course, those extra turns will also add quite a bit of stray capacitance between turns, so you may not be able to reach the top of the band at minimum tuning capacitance.

What kind of insulation is on the wire in the big loop? Its thickness and dielectric constant have a big effect on the total stray capacitance each turn will add.

I don't think it is as effectice on SSB. Of course, you can use the
symbols that were derived from CW (like QTH) but I think morse code is a
more direct communication in these circumstances because it doesn't
involve voice/pronunciation differences between languages. The symbols
are universal and immediately understood.

Phonetic usage (alpha bravo whiskey hotel etc) is primarily based upon
English.

I think we need to face the fact that ham radio, in general, is not as necessary or as "needed" as it was even 20 years ago.

It's a hobby. It remains a service but it is a hobby.

CW,SSB and any other mode you choose is not that much NEEDED.

CW being the simplest form, remains the form of choice when ALL infratructural resources are gone.

Memorizing a sound is no more of a skill than memorizing an answer. In any case. I can memorize sounds. I can't memorize answers. I have to know the subject to get the answer right. If people think that CW is of any importance, they will learn it whether the test requires it or not. Those who think that it will die if it is not required are just afraid that it really is useless.

2046. Voltage BalUn Frequency Range

Newsgroup: rec.radio.amateur.antenna
Date: 2006-05-06 15:38:57 UTC
From: John Popelish <jpopelish@rica.net>
Message-ID: <-YGdneFEO4LqXMHZnZ2dneKdnZydnZ2d@adelphia.com>
Source record: 59884

I am trying to understand how to estimate the frequency capability of a voltage BalUn made by winding two insulated wires, in bifilar fashion, around a ferrite core.

For instance, I have made one, with two 23 turn windings, that exhibits a paralleled winding inductance (at 253 kHz) of about 568 uHy. The two windings in series aiding, exhibit (at 119 kHz) 2550 uHy. The two winding in series bucking, exhibit (at 5.7 MHz) and inductance of 1.15 uHy. And the capacitance between the windings is about 154 pF. The total wire length in each winding is about 1.2 m.

Neglecting for now, the high frequency roll off of the ferrite material (which is similar to type 43), is there a way to estimate over what frequency range this voltage Balun will act as a fairly ideal transformer, based on these measurements?

Thank you for your assistance.

2047. question: NEC2 w/ ground parms.

But being able to pull up the correct characters from memory at the pace of an incoming stream is a skill.

I have an 85-year-old uncle who was a cw operator in the Pacific in WWII. He hasn't done anything with cw since 1946, and he can still copy around 10 wpm when I make him a bet.

I can go for several years without hearing cw and still step in and copy 15wpm easily.

Those of you who once passed 20 wpm tests and now find it a challenge to see if you "remember any of the characters" are simply not very bright.

For either line-of-sight or multi-hop propagation through the
ionosphere -

- this apparently simple program computes path loss in dB between
transmitter and receiver, field strength at the receiving site, and
receiver S-meter readings. Transmitter power output can be varied
between 10 KW and 1 milliwatt.

It is educational for newcomers and of assistance to DX and
line-of-sight experimenters. It illustates how S-meters OUGHT to work.

Download program PROPGATE from website below in a few seconds and run
immediately. Its at the bottom of the list.

I once made a J-pole from 300-ohm twinlead and tweaked it until it worked
OK while hanging from the ceiling, but when I moved it over next to a
wood-framed picture window (hung it from the window casing), the SWR went
to pot. Did I do something wrong?

(I concluded the J-pole must be VERY sensitive to its surroundings.)

a damped LC ???
Does it make sense to introduce a R in the LC circuit and use it as
antenna ??
Does it change eg the Q ??? etc ...

I have tried to put formula's here
(look if they are right !
freq_low=Math.sqrt(1/(inductance*cap_high) - (resistance * resistance)
/ (4 *inductance *inductance))/(2*Math.PI)
freq_high=Math.sqrt(1/(inductance*cap_low) - (resistance * resistance)
/ (4 *inductance *inductance))/(2*Math.PI)

OK ???
)
http://users.fulladsl.be/spb13810/amlooprlc.htm

A high R seems to lower the low freq, that's interesting ...

original formula for LC circuits: (put R = 0 in previous, and you should
get the same ....)

The lower Q makes the LC less selective. For a tuned loop, it is not a
good idea to introduce resistance.

Any rational evaluation of the modes available will show that there is a
combination of circumstances that make a specific mode the one that will
"get through". One can "prove" that their favorite mode is the one that
will get through under certain conditions.

Have you measured the signal strengths from a few stations of known
locations, power levels, and antenna gains, and compared them with your
program's predictions?

Sounds like ordinary PVC insulated hook up wire. The PVC is a little
lossy, but not too bad at this low frequency. You would have a lot
more trouble with high capacitance if you were using enameled (magnet)
wire. My favorite for such things is Teflon or Tefzel insulated wire
(low loss and low dielectric constant), but it is expensive and hard
to find. Another good, but hard to find insulation is polyethylene.
It is sometimes used in low capacitance, data grade cables, but
stripping out enough for this project would be a career.

Do you think it is practical to pull 6 more turns through your pipe?

Are the formulae used in this program approximate and perhaps do not apply in circumstances in which you have no time (at this time in your life) to tell the "secrets" about? Without source code, it is difficult to "read between the lines".

John

I have seen PACTOR II get through from Europe with 10 watts
when there was no humanly detectable signal. All I did was
choose the correct frequency and time based on a schedule.
I detected absolutely no carrier on the S-meter or with
my ears in CW mode. The PACTOR II signal was literally
down in the noise but my SCS PTC-IIe somehow managed
to dig it out.

As an avid 4WD SUV owner I do a lot of outback travelling (Austrlian Deserts, Cape York, Kimberly Coast) and as such have a Barrett 950 HFradio &Barrett 910 Autotune antenna installed for comms.

Would it be preferable when camped / stationary to earth the vehile to a "ground" ground = what I am looking for is a better receive signal ?????

********** REPLY SEPARATOR **********

Improving the ground will increase the received signal strength but
will also increase the background noise as well, so the signal to
noise ratio won't change much if any. In other words, no real
improvement.

However, an improved ground will improve your transmitted signal,
especially on the lower frequencies - 7MHz and down.

Best of all though, would be to string up a temporary dipole or
inverted vee.

Have you tried manually calculating the complex dielectric constant? If
there is a
difference greater than 10E-3 from the GN card an error message is
generated.

From your information above the difference is >> 10E-3. pp 55, 56 NEC 2

It depends on what you want. Maybe the bandwidth is to narrow or the
tuning action is so sharp it is hard to peak it. You add resistance and
the peak does go down but the bandwidth also widens.

Here is a link to one I have had good luck with. Works quite well out
of the box. I use two chaokes, one at the base, and one 19 inches below
that. You may need to trim the length of the half wave section, so cut
it a smidge long.

Dee, please go back and re-read Silent Key's original post and my response.
I was reacting ONLY to that one person's remarks. I was actually
narrow-brushing.

While I'm an officer in just one club, I am in three and none of them have
any crummy people -- and I certainly agree with you that many amateurs don't
jab the techs. In fact, I encounter practically total acceptance. That's
why Silent Key stood out.

With regard to can/can't learn, I have the most problems with the characters
that are four or more elements long. dit-dah-dah-dit and dah-dit-dit-dah
are different, but I can't tell you what they are. I think one of them is

"P" because I remember the symmetry.

Transcribing is not the problem. If I hear dit-dah, I can write A. But if I hear dit-dah-dah-dah-dah or dah-dit-dit-dit-dit, I don't know what to write, because I don't know what those are. I cannot store the memory of what those sounds mean. Since you (apparently) don't have the problem, you won't relate.

And it isn't a lack of time or effort. I have been at this since 1993. Many methods. No appreciable successes. (I did get "D" from "dog-did-it" and "Q" from "pay-day-to-day" -- a couple of real triumphs, eh? [sarcasm intended])

This is no picnic. Thanks for understanding.

73,
"Sal"

From: Kevin & Natalia <sparc_man@hotmail.com>
Message-ID: <1146994748.542651@ftpsrv1>
Source record: 59918

Hi,
I want to build a new antenna.
The design I have seen is a 3 wired type each side, where the 3 wires join together at each end.
There are two of these, and the two are centred, and fed with coax.
The one I saw was flat, but understand that they could be in-verted.
I am hoping it is multi-band :)
I would like to find information on this antenna, measurements, and construction hints.
If anyone can help, could you please advise.

Regards in advance.

Kevin, ZL1KFM.

Amen!

I used to be a staunch defender of CW. We lost the 20, we lost the 13, we are going to lose the 5.

In today's age of materialism, self created rights and the liberal ideals of fairness, I'm just waiting for the removal of all testing requirments.

Just show up, mark A, B, C or D on 10 questions (no grading, just turn it in) and then get a certificate of attendance, a blue ribbon that says 1st place and a 1x2 vanity call sign.

Guy

That is correct. Let's just take a very simple example. PSK is one of our
newest digital modes. When there are auroral disturbances, PSK cannot be
used. The phase shifts induced by the auroral activity make it impossible
for the computer to read. These phase shifts effect all the modes. Modes
that depend on phase shifts (such as PSK) are affected the most severely and
quickly become unusable. On the other hand, CW takes on a buzzy, raspy
sound but a human operator can still decipher it although a computer will
fail. I have personally experienced these conditions. If the auroral
induced phase shifts aren't too severe even SSB will get through when PSK
has failed. I have also personally experienced this.
```

Let's take another. This time packet. Packet has nearly died out on HF because it is not robust enough. Conditions have to be almost perfect for there to be a usable packet signal. Even low levels of atmospheric static make it unusable. Slight fading also causes problems. Yet voice, CW, PSK, and RTTY will all cope with conditions that can make unusable.

Each mode has its strengths and weaknesses. For each mode, there are conditions for which it will be the best choice and conditions for which it will be the worst choice. If a person wants to maximize their communication capabilities, they need to become conversant with each mode, its characteristics, and what affects its propagation. For CW, this should include learning to copy by ear. Under some conditions, the human brain is the only computer powerful enough to decipher it.

In the USA there is no limit on antenna hight related to the 2.4ghz band.
Just remember you DO have limits on ERP.

There are restrictions on antenna heights based on building codes where
ever that tower may be located as well a Over all FAA Restrictions but
those have nothing to do with the radio bands being used on the tower.

I suspect that antenna is a collinear antenna with elevated Feed.
Probably 1/2 of the of the antenna or more is simply transmission line.
They want the active elements be to in "Free Space" above any surrounding
equipment.
Its amazing what people will do with electronics and wonder why it does
not perform as advertised.

Switching to a Dipole antenna suspended from the trees would be a Major
step upward in performance.

Mobile antennas have very low efficiency, grounding them will not improve
that significantly relative to the dipole.

What are the typical distances you want to cover?

Below 7 MHz and at distances in the hundreds of miles, relatively low,
horizontal antennas may perform better than a vertical whip, even if
only the same length as the whip.

If you were in this area, I would be more than happy to take a try at teaching you. The "dog-did-it" approach is one of the worst possible ones to use. It is like trying to count the dots and dashes. On longer letters it can be a problem.

For someone like yourself, it is absolutely essential that you eliminate any and all extra translation steps. The burst of sound should register directly as a letter. In other words, hear it as a letter and reflexively write a letter. Then it doesn't matter if you happen to know the actual number of dots and dashes. No counting, no "dog did it", no "helpful" memory devices at all. They will only hinder someone like yourself.

> This is no picnic. Thanks for understanding.
>

Well I just wish that I could take a stab at teaching you. There is always a sense of accomplishment in expanding your abilities in ham radio. For example, in the past couple of years, I've been exploring the digital modes and VHF/UHF propagation. It's a hoot to work Texas on 2m from here in Michigan.

Complete nonsense. CW testing is being phased out because CW is
becoming obsolete, period. Don't try to read anything more into it
than that.

With all the great new digital modes available - most of which are far
superior to CW - forcing people to waste valuable hours learning an
obsolete mode is sheer folly. There are so many great things to do
with Amateur Radio. Do them!

Quite correct Bill. Commercial and military have dropped Morse code
for the very reasons you stated.

In this day and age, requiring proficiency in Morse code for a radio
license would be as requiring proficiency in horse husbandry in order
to get a driver's license.

OK folks. All I hear is whining about how things are changing. So I'll ask the question again.

If you really believe that morse code is an important way to communicate that should be preserved then you need to convince other hams and potential hams to learn the code. You need to convince enough

hams to use code so its very usage generates excitement and makes people want to join in the fun. Almost self-perpetuating like it was in the 1950's.

Preaching (or complaining) to the choir on the radio fora about the abysmal state of things will not add one person to the ranks of key pounding hams.

So what are you going to do to increase the number of code practicing hams.

Don't you find it odd that people need to be "convinced" to use morse?
Nobody needs to be "convinced" to use PSK31, RTTY, SSB, FM or even AM.

Life is too short to waste it "convincing" people to use a mode they
are instinctively not interested in.

The underlying problem is you want things to be like they were back in
the '50s. Well, I was licensed in 1957 and I had fun back then too,
but time marches on. Try marching along with it.

Actually if you go back and re-read the entire message I think that
between the lines you might pick up that I think these guys are living
in the past. CW is all but dead and buried. All professional users of
consequence have abandoned it.

I have the same problem with the code. My brain wants to identify or
count the dit/dahs and then translate them into the character. Learning
each character as a quick burst of sound, as if it were sent at an
equivalent speed of perhaps 20-wpm, is probably the best method.
I never got beyond about 10-wpm after practicing on and off for many
years, sometimes for months at a time. I used to listen to the code
practice transmissions on W1AW every night. If the 'General' code
requirement had been 3-wpm less, I might have been a ham' decades ago
but I wanted HF phone privileges or nothing (stubborn me). I didn't have
any interest in getting a Technician license or being a Novice until it
expired because of my code limitations. I don't think learning the code
has much to do with intelligence or even motivation to a certain extent.
Some folks are just not wired for code. I could have passed the Extra
exam' in the days before the questions were available to be memorized
but that 20-wpm was the problem. I tell myself it was amateur radio's
loss. :-)

It certainly does. One of the ways to calculate Q is
Resistance/Reactance. By definition, increasing resistance will lower
Q.

Q is also the bandwidth/frequency at the point the signal is down to
half peak.

Source record: 59737

I have been looking for a UHF only outside TV antenna or plans on how to construct a double bow tie like antenna. Right now I have a 50 foot short run of RG-59 to an upstairs patio post. At the end of the coax run I user an old TV antenna transformer to interface to the 300 ohm lead from a single bow tie (that came with old TV). This setup works but surely there is something better. We are not that far from the transmission sites but an inside antenna will not work.

Most Radio Shacks still sell the Antenna Craft OEM - UHF product.
Top of the line (mfg) is Weingard product (BTW both made in Burlington, IA)

2098. Re: J pole question

Newsgroup: rec.radio.amateur.antenna
Date: 2006-05-07 20:32:45 UTC
From: F4DRH <F4DRH@wanadoo.fr>
Message-ID: <445e596a$0$21305$8fcfb975@news.wanadoo.fr>
Source record: 59739

Hello Harbin

The bottom of the J-Pole antenna is a 1/4 wave length to transform the high impedance of the 1/2 wave length above into a lower impedance (close to 50 ohms). The impedance of that 1/4WL sould be Z = SQUARE (Z coax X Z antenna) .... in that case Z antenna is the impedance of the 1/2 WL (usually several hundreds ohms)
That's why the space between elements as well as there diameter is important.

You certainly know the Topfkreis ... which is the same antenna ... 1/2 WL + 1/4 WL ... but with another technical realisation.

Hoping it helps.

Howdy:
In a j-pole the 1/4 wave element, and the bottom 1/4 of the 3/4
element should act as a transmission line, right? So... shouldn't these
elements be as very close to each other to cancel one another out, closer
than what I see on most j-poles? Or is this space have something to do
with the impedance of the antenna?

Our True Value hardware store has them.... then again, we
only have UHF TV translators here in where I'm located so maybe that is
why they stock them.

I believe Radio shack has a model available, too, but the
double stacked bow-tie antenna I bought for $24 at the hardware store was
superior.

2100. AM/MW Loop Antenna - Inductive Coupling -vice- Resistor Spoiler

Newsgroup: rec.radio.amateur.antenna
Date: 2006-05-07 21:57:19 UTC
From: RHF <rhf-newsgroups@pacbell.net>

Switcher,

AM/MW Loop Antenna - Inductive Coupling -vice- Resistor Spoiler
http://groups.yahoo.com/group/Shortwave-SWL-Antenna/message/9407

To some degree all Circuits are L+C+R
- - - Although anyone of the three may not be significant
enough to factor into the Circuit Design parameters.
- - - Hence an AM/MW Loop Antenna is simply presented
as an L+C Circuit.

"IF" you were to use a Resistor in the Circuit of an
AM/MW Loop Antenna it would be 'because' the Radio
that you were using it with was being OverLoaded by
the Signal from the Loop Antenna.

You could simply achieve the same thing by varying the
AM/MW Loop Antenna 'coupling' with the Radio -by- Moving
the Loop Antenna nearer-to -or- farther-away from the Radio.

AM/MW LOOP ANTENNA COUPLING :
* The Coil of the external AM/MW Loop Antenna
is an Inductor {RF Transformer Coil}
* The Coil of the Radio's internal AM/MW Antenna
is an Inductor {RF Transformer Coil}
* Together the Two Coils form an RF Transformer
Moving the Two Coils and changing their relationship
to each other varies the "Coupling" between them.

RESISTOR AS A SPOILER IN AN AM/MW LOOP ANTENNA CIRCUIT :
-However- If you must use a Resistor in the Circuit of the
AM/MW Loop Antenna - Consider using a Series 1000 Ohm (1K)
Potentiometer (Pot) - So that you could adjust and fine-tune
the Circuit to achieve the Maximum Signal without OverLoading
the Radio. Hook the "Pot" up with the two ends connected
together and the Center Wiper as teh other end of the
Resistance Element of the Circuit. With the Wipper at either
end the Pot is out of the Circuit. As the Wiper is moved
from one of the ends to the Center of the Pot the amount
of Resistance in the Circuit 'increases' and the RF Signal
{EMF Field} of the Loop Antenna is Decreased. Wiring-Up
the Pot this way makes the Resistance Curve non-liner from
"0" to 500 Ohms sort of more like an Audio Taper Pot.

If you search the archives of this group (for example with Google), you wil find some good info about loops for low frequency reception. One way to keep the loop's effective self capacitance down is to wind it with the wires spaces apart some. It is common to use at least one wire diameter spacing between wires, so it would be at least two times the wire diameter, center to center. You can also put, say, 11 pieces of wooden dowel or PVC pipe in a circle. Number them in sequence. Then wind the wire outside 1, inside 2, outside 3, ... outside 11, inside 1, outside 2, ... so that each successive turn is on the opposite side of each particular pipe. (The axis of each pipe is perpendicular to the plane of the circle.) As you can see, you must use an odd number of posts in this construction.

There is benefit to making the loop very symmetrical about a vertical plane, because local sources of noise are likely to be electric field which is perpendicular to the earth, and will be rejected by such a symmetrical antenna.

Cheers,
Tom

home depot has "HDTV" antennas. They are primarily UHF with a couple
of VHF elements scattered in them. They, or Lowes may have what you
are looking for.

Also 300 ohm twin-lead, if properly installed, will bring in a
stronger signal than the coax will.

hope this helps

I've got one of these.

http://www.starkelectronic.com/wnpr8800.htm

The half-size (4-bay) would probably do it for you.

With a Channel Master 7778 pre-amp I'm receiving all of the Phoenix
hi-def channels from 100+ miles away.

Probably just the pre-amp would fix your problem.

In the olden days, the purpose was well understood. It was, and still is, to become proficient in one or more aspects of radio communication, to provide a skilled base of technically proficient people who pursue an interest in some aspect of radio communication technology and art for personal gain without any financial interest, reward or compensation from the activity.

It is NOT to open a box, plug it in, connect a wire, and, when it doesn't work, get on the internet and ask for help.

I advocate for a code test for the following reason. I value what I have to plan for, work for, sacrifice for, and invest my time for.

I value the reward for 18 months of practicing Morse Code every night for one hour a night. That's an investment.

I value the reward of studying, really studying, to understand the electronics for my Technician License. That's an investment.

I value the reward of studying, really studying, to understand the electronics for my General License. That's an investment.

I value the reward of studying, really studying, to understand the electronics for my Advanced License. That's an investment.

I value the reward of studying, really studying, to understand the electronics for my Extra License. That's an investment.

It took me 45 years to progress from Novice to Extra. [Note: I was 25 wpm CW proficient in the 1960s. Marriage, Family, Profession took priority over Ham Radio.]

I teach Ham Radio classes. I'm a registered ARRL instructor. I'm not invited to teach too often in these days. I DO NOT teach Q&A. I WILL NOT teach Q&A. I teach understanding of what's behind the Q&A.

My Technician classes begin with ELEMENT 1. It takes 3 to 4 weeks at two hours a week for classes to pass Element 1. It takes 10 to 12 additional

weeks of a two hour class one night a week plus homework to pass the Technician exam.

Those who choose this path have made an investment of their time and effort. I hope they value that investment.

I WILL NOT support a 4 hour session on a Saturday morning and hooray! You are now a ham!!!

BTW, FWIW, I'm still learning from the skills and experiences of Roy, Cecil, Rick, et al on the antenna n.g.

/S/ Dave, W1MCE

I do not believe anything will improve the receive on the antenna you
are using, what ever it may be. If you are going to be parked, put up
"stick dipole" just as high as you can. That will help recieve and
transmit.

OK, I did a search, unsuccessfully, on Topfkreis. What is it and
where do I find it?

thanks

You could have shortened that up considerably. Short version: "I did it so
everyone else should have to". See how easy that was? Not an original idea
though.

If the tuned loop bandwidth is to narrow then you can deliberately
spoil the Q of the loop by adding resistance and broaden the bandwidth.

I have not calculated it but I expect a LC loop operating in the MHz
range would have a bandwidth greater than 12 KHz so I do not expect you
will have a problem.

A really quick back-of-the envelope look at the problem indicates that adding a resistance won't make the signal any stronger when the loop is tuned away from the peak. It'll just make the signal weaker when it is tuned to the peak. So it's "wider", but no better at any tuning setting but worse at and near the peak. To check on my calculation, try it: connect and disconnect the resistor at various tuning settings, on and off peak. Does it make the signal any stronger at any setting?

The only time there would be any advantage to adding an R to widen the bandwidth is if it's so narrow that it distorts a modulated signal due to uneven response across the audio bandwidth. This would mean at least several dB variation over a couple of kHz for voice SSB or over 10 kHz for broadcast quality AM.

I read his post correctly his concern is a 12 KHz wide DRM signal and
that the tuned loop response will be to sharp and narrow. Firstly he
needs to build the loop and sweep it to see if has a problem to begin
with. Parasitics may cause the loop response to be wide enough that 12
KHz will not be a problem. If it turns out it does he can add
resistance, which will decrease the peak response and broaden it. Adding

resistance will cause the loop to not work as well but that is the price you pay for greater bandwidth.

Normally the best thing is to over-couple the loop to the receiver,
rather than loading it with a resistor.

The Q of the loop is not only a function of the loss resistance and L/C
values, it is also a function of the loop loading caused by the
feedline/receiver combination. That introduces resistance to the
system.

Adding a resistor is the last think I'd do. If I had a bandwidth
problem in a resonant loop, I'd simply overcouple to the feedline and
let the feedline/receiver resistance load the antenna.

The only problem with the EEs that I run across, is they know just enough to
get themselves hurt and/or burn their homes down when they try to work with
ELECTRICITY instead of electronics. It seems that at 240vac, all their
common sense goes out the window.

> I, sometimes).
>
>

That is exactly the point I was trying to make. If one is content to turn
off the radio and not communicate at times when signals are distorted, then
various modes become less important. But I prefer to be able to communicate
as long as possible. Thus I consider it part of my goals as a ham to be as
conversant with as many modes as I can. I have setup and operated the

digital modes, including building my own sound card interface (even though I don't normally attempt soldering), just to gain experience in them even though I have no real interest in operating them per se. Pounding away at a keyboard is too much like the internet or my job.

To clarify, specify the conditions, and the "best mode" becomes evident. With distorted signals, CW wins with voice coming in second. With weak signals, some digital modes win with CW coming in second. For power consumption for a given signal strength, the digital modes come in last since you must have power to run the computer. And the power to run a computer alone (depending on the computer) is often more than enough to run a 100w CW or voice signal. So you add the digital signal and the digital modes become "power hogs."

Every mode has value.

I've got an older rat shack corner reflector yagi/log thang that
is fairly decent. But I don't know if they sell them anymore..
It's the same basic antenna as the UHF section that you would
get if you bought the big UHF/VHF antenna.
The one I have has a corner reflector with 10 total elements.
Then it has the driven element, and about 14-15 director
elements that are all the same length. I used to to
receive the local UHF ATV machine. It was great for dx though
when the band opens up with ducting in the summer. I'd
watch stations all over the place from Houston. IE: San Antonio,
Austin, Corpus, Little Rock, West memphis , etc..
The ducting on UHF is actually even hotter than it is on VHF
most of the time. If 2 meters opens up, check UHF TV...
Half the time it will be wide open. The antenna I have would
eat the average bowtie for lunch. But like I say, they may
have quit selling them.

> to each other varies the "Coupling" between them.

Nice reasoning, but:

When coil A - ant has 5 turns, and coil B - radio has 5 turns, the
voltage (or so) is the same.

When we now double A / or B, the voltage should vary for the same
amount, I learned.... so you can make the sig higher ???

In my physics book (Halliday/Resnick Fundamentals of Physics), p 445 -
transformers it says:
N1 / V1 = N2 / V2

would it be possible to double the number of turns on B (which is
sometimes easier ... space requirements) ??? That would lead to double
V2 and higher sig ... ???

Of course, problem remains ... resonance. You can't add tunrs to A, or
you loose resonance ... Adding turns to A means .. making it smaller
... to have the same resonance properties ...

Here's a very simple end fed vertical dipole:

http://www.la2t.org/otfgallery/albums/Teknisk_plukk/1002.jpg

http://f3wm.free.fr/radio/pocket.html

It's simply a piece of coax. The braid is stripped off the last 1/4
wavelength. Another 1/4 wavelength from the end, there is a choke to isolate
a 1/4 wavelength of braid from the rest of the cable. Presto, dipole!

Support it with a fishing rod, hang it from a tree, whatever.

Dave, W1MCE, BSEE [ElectriCAL Engineer]

Never worked as an electriCAL Engineer. Designed transistors for almost four years. Designed USAF Flight Line Test Equipment for six plus years. Designed USAF Computer Controlled Avionics Test Equipment for 10+ years. Spent 3 1/2 years as Field Engineer at Hill AFB, UTAH on Computer Equipment. Worked for 7 plus years on the Effects of Nuclear Weapons on USAF strategic assets. Spent part of three years at the Nuclear UGT facility in Nevada. Spent 6 plus years as Chief Engineer on the USAF MX Missile RS/RV. Finished up as System Engineer on the RF Subsystem Force Modernization for the MK21 RV. In between, I managed the Strategic Product Design, Electronic Department for three years, now retired.

I still have my text books on HV transformer design, Generator Design, Fluid Dynamics, Thermo Dynamics, three phase power distribution, etc. around here somewhere ... I hope.

My VP Engineering, to paraphrase his judgment, claimed: "Give me an Engineer with a good Physics background and a good Math background and I can put him/her to work anywhere. In three months [s]he will be blunder proof, in six months competent, in 12 months expert." After 30 plus years of engineering I conclude he was correct.

But, I've left BSEE behind me. I retired from my profession six years ago.

And, as my wife says; "You can take the engineer out of engineering; but, you can't take engineering out of the engineer." I'm still learning from highly gifted people like Roy, Cecil, Reg, etc.

I'm still practicing my Vocation ....

CW, you are incorrect. I VALUE my license because it took effort over many years. The issue is valuing your license because you invested time, talent and energy into obtaining it. The more you invest, the more you value.

If you read the full message you would conclude that the message is about investing and reward of investing. It is not about a 4 hour cram short term memory program that yields a Technician License without the KNOWLEDGE of how to build a 1/2 wavelength dipole with coax to connect to the new out of the box toy.

When I read posts regarding 'how to ...' on some basic aspect of Ham Radio I wonder about the training, education, understanding, that went into 'studying' for that license. IMO, the license should indicate a level of proficiency that, in many cases, is missing. When I hear an EXTRA CLASS ham on twenty meters asking someone what the difference is between USB and LSB, we have a problem in training and education.

I don't know if Ham Radio will degenerate into glorified CBers. But, for many it has become a hobby of appliance operators.

If you really believe that morse code is an important way to
communicate that should be preserved then you need to convince other
hams and potential hams to learn the code. You need to convince enough

hams to use code so its very usage generates excitement and makes
people want to join in the fun. Almost self-perpetuating like it was
in the 1950's.

Preaching (or complaining) to the choir on the radio fora about the
abysmal state of things will not add one person to the ranks of key
pounding hams.

So what are you going to do to increase the number of code practicing
hams.

I did not study for my tech test at all (beyond a quick reading of the
pool I worked from memeries of my failued efforts 2rogh twenty years
before to obtain a Novice lense

and what reward from Code, I have invested in my teen when I could that
sort of thing 5 years at 40 minute perdays 5 week aweek and I got
NOTHING for it. (except that one of the ham giving the test noticed
from the patern in my error I might be dyslexic and I got what
treatementthier was much sooner than i would goten otherwise)

you idea is premised on the theory one get what one pay for and gets
paid what oneis worth. You kknow what ome of us have never found that
to be true I have never gotten a fair rate of pay I have always been
more than I was worth or less than I was worth

I value profit, my tech licesne has been a profitable insvestment,
exceming so, Hf has been a balck hole for effort yeilding NOTHING for
that effort

indeed I am not esp interested in building rig myself more intersted in
interfacing radio with their part attennas and such

indeed I have even been intered in the possibilities of what I call
human assist machine decode of CW I have made contacts where the
machince decodes what it can and I look at a screen to decide is that a
dit, dah or satic, feeding the results back in the machine for clear
text, done that hispeed metro stuff and that has acheived my 3 EME
contacts

all without any real abilty to decode by ear the cw itself beyond
needing to tune the signal

CW is and might be around forever for identifiers in different things.
It can be transmitted along with voice and doesn't get in the way
of other things. Any loss would be the best fun I had during
my Amateur Radio Service and learning Radiotelegraph Second class
training. I even found a code chart at the RF desks at a NASA MSFN tracking
station when I worked there. Just in case!

Fascinating! We have here a perfect example of a functional illiterate
who was able to obtain a Ham license. Of course he would not like CW as
one must be able to spell, and construct simple sentences, which is
obviously beyond him.

Hi,

Indeed a worthy offering. <G>

Also feel free to download and use the default QSL-ware (freeware) WinCAP Wizard.

WinCAP Wizard is an enhanced, amateur radio directed, HF prop app making use of the VOACAP prediction engine.

Many, many charts and reports are provided in the QSL-ware mode.
www.taborsoft.com

Cheers,
Jim

Also try Googling for "sperrtopf" or "sperrtof". Same basic idea...
a J-pole-like extended Zepp in which the matching section is a coaxial
sleeve.

Whoever you are,
I believe you will find this in the book about the early days of amateur
radio. It is called something like "200 Meters and Down", or is it "Below".
ARRL has it and many ham stores do. I have a copy and have difficulty
remembering the exact title. A really nice read. I also have a 1932 ARRL
handbook and I think there are references to the "doom of the advent of CW"
in there also.

. You, of course, know about spark. The sparkies didn't like CW and, at
that time, the FCC __DID__ out law it (spark, that is).
I admit that it was a loaded question because CW stands for Continuous Wave
and what differentiates it from" Spark". Probably not what the troll wanted
and I know he/she/it wouldn't respond, but did it anyway.

> > Your fingers and eyes (or ears) aren't broke....

Even if you went to the trouble of pounding in a 3 meter (8 ft) ground rod,
or laid out somewhere between five and 40 radials, the answer would still be
NOPE. As stated in other posts, the loaded mobile antenna is in-efficient
to begin with.

73, Steve, K9DCI

Well, knowing RF, it 'might' make a measurable difference (small amount),
but probably not a practical difference (many dB).

Harbin,
You seem to understand the "J-Antenna". What you really seem to be asking is how far apart is "too far" for a balanced transmission line. That's a question I can't answer and I'm sure others can, but , in the common custom of adding obtuse references which sort of seem to be relevant... what about that old one wire transmission like the "G-Line"? [no joke]

73, Steve, K9DCI

"Harbin" <harbinjr@adelphia.net> wrote in message
news:d92dnVBi_rDdB8fZRVn-hA@adelphia.com...
Howdy:
In a j-pole the 1/4 wave element, and the bottom 1/4 of the 3/4
element should act as a transmission line, right? So... shouldn't these
elements be as very close to each other to cancel one another out, closer
than what I see on most j-poles? Or is this space have something to do
with the impedance of the antenna?

The FCC Outlawed 'Spark' for very valid technical reasons
at that time and they are still valid today. The very same
logic could be used to still justify the continued use of CW
as an Amateur Operating Mode; even though the requirement
for proficiency in CW is not used for an Amateur License.

My arguement for CW has never been from the perspective of getting more
ops. It's the quality of the operators I'm concerned about, not quantity.
A code requirement may mean someone will study the theory portion a
little more while they're building up their code.

One day, when you turn on your HF or VHF/UHF rig and it sounds like CB,
you'll understand where I'm coming from.

I'm going to drop this agrument because it looks like I lost and people
really don't care anymore one way or the other, but I'll end it with just
couple questions to all;

What is one behavior on our ham bands that might or could make you loose
interest in ham radio and leave if you heard it or if it became previlent?

And does it seem like it's going that direction?

So, are you asking if people are getting rude, using foul language and don't seem to give a crap about each other? If so, yes, they are. The sure cure for that would be to increase the code requirement to 30 words per minute for general. Faster for extra. Along with that, NO license of any kind without an engineering degree. This all wouldn't do anything about lousy operators. What it would do is reduce the number of new hams. After a while, we would be down to 100 or so nationwide. The bands would get much better because there would be virtually no one using them. Something that you seem to have failed to consider is that society in general is adopting these traits you find objectionable. New hams tend to be more objectionable (under this criteria) than old. Is it because they didn't spend hours studying code? No, it's because they are products of the society they live in. Americans are known worldwide as pushy, arrogant, self centered bastards. There is a reason for that, they are.

Switcher,

For most applications using "Receive Only" Matching
Transformers (MT) the Idea is to step down the Voltage.
If the Antenna-Side of the MT has a Voltage difference
of 0.9uv (Weak Signal) to 180uv (Strong Signal) and the
Receiver-Side of the MT would have a Voltage difference
of 0.3uv to 60uv which most Receivers could better
handle.

It is my simple understanding the two things that we
wish to accomplish with the Receiver-Side of the
Matching Transformer is to Match the Impedance
of the Receiver's Antenna Input for the Range of
Frequencies we hope to hear and to adjust the RF
Signal 'differential' to better match the Limits of the
Dynamic Range of the Receiver's Circuitry.

Ozzie,

What the hell...give it a try. Your only investment is a little time, a little work pounding the ground rod in, and it'll work or it won't. Then, have a beer, sit back and enjoy the night.

Personally...I think if you are just interested in listening...try tossing a long wire in the bush, and maybe wrapping the other end, a dozen times maybe, around that 2m steel whip.

Gud luck mate

My point was that few people here think beyond the dipole, quarter wave
vertical, or shortened mobile vertical. And all of those for HF. The
group is broad minded in many ways, but very narrow in others.

No license without an engineering degree would be fine by me. And
follow it by one that requires complete knowledge of the National
Traffic System. Which would be more inportant by far if you want to
keep the traditions up.

How many here know how to pass traffic properly? Bet I can draw a line
in time. And it had nothing to do with license class. I was a tech at
the time. But I learned how to pass traffic, and how to be net control
as part of the NTS. Because I had people on our local nets that
enforced the rules. On checking in, out, and passing traffic. Traffic
up into the system, and down to the final recipient.

That, my friends, was the difference. Not CW.

news:445e596a$0$21305$8fcfb975@news.wanadoo.fr...
Hello Harbin

The bottom of the J-Pole antenna is a 1/4 wave length to transform the high impedance of the 1/2 wave length above into a lower impedance (close to 50 ohms). The impedance of that 1/4WL sould be Z = SQUARE (Z coax X Z antenna) .... in that case Z antenna is the impedance of the 1/2 WL (usually several hundreds ohms)
That's why the space between elements as well as there diameter is important.

You certainly know the Topfkreis ... which is the same antenna ... 1/2 WL + 1/4 WL ... but with another technical realisation.

Hoping it helps.

Regards

Jean-Marc

Hi Tom:
The Topfkreis kind of reminds me of the skeleton sleeve antenna.
Very interesting.

I don't know if it is the same article, but I read about someone who
connected two cars and added a little wire to make up a 20 meter
dipole.

It's actually a good thing when folks come over from "the Dark Side". When new to Hamdom it's almost certain they'll slip up and occasionally use their old "jargon". When they correct themselves it's also a good thing, since it means they are aware of their faux pas and are working at improving their operating procedure and language.

Harbin,
You seem to understand the "J-Antenna". What you really seem to be asking is how far apart is "too far" for a balanced transmission line. That's a question I can't answer and I'm sure others can, but , in the common custom of adding obtuse references which sort of seem to be relevant... what about that old one wire transmission like the "G-Line"? [no joke]

73, Steve, K9DCI

Hi Steve:
I have read about the G-Line, which is very low loss (so claimed). Have
you heard of anybody that has used this line?

> EN
>

My first observation is that your soil conductivity is < zero.
Should always be > zero (GN card should be: GN 2 0 0 0 12.0000
0.007).
I am certain that this would give you the kind of error messages
you are seeing. The program actually runs under these conditions, using
Nittany's NEC-Win Pro,
but produces erroneous results -- input impedance, radiation patterns etc.

Correcting the conductivity gives much more realistic results: resonant at
6.8 MHz,
Zin 700 ohms, classic dipole pattern.

Your segmentation is probably a bit low for such close proximity conductors,
also
the segment sequence could be improved, but not important unless you want to
graph the conductor currents. I would suggest making the conductor segments
equal to the triangle side lengths. This may change the results a little,
but the
correct sign for conductivity will make a big difference.

Regards,

Frank

>vertical, or shortened mobile vertical. And all of those for HF. The
>group is broad minded in many ways, but very narrow in others.

Oh, I think people think about them. They probably just don't talk
about
them as much. You think I'm stuck to HF? Wanna come look at my
latest 144 yagi that is nearly as long as the f/b width of my house?
"30 ft boom"
Seems I just commented about rat shack UHF antennas yesterday if I
remember right. I usually talk about what other people talk or ask
about..
To tell the truth, I'm about bored with the whole mess, and don't post
as
much about any kind of antennas as I used to. I've got so many sticks
in the fire
lately, ham radio is just one wee small area I mess with. And I'm
getting more and
more bored with it every year. I used to be able to do 55-60 wpm on CW
in the
late 80's.
But due to my lack of activity the past few years, I'm slipping down to
snail
pace CW. Now I can only do about 35-40 wpm, and it gets a bit slower
every
year. If you want to talk about different topics, it's up to you to
start them.
We can't read your mind on the internet...

> guess it is technically a monopole.

Sort of, sort of. The feed point is actually in the middle of the half wave. Traditionally, it's called coaxial sleeve antenna. Except originally, the sleeve was outside the coax braid. In this variation, due to LA1IC Rolf Brevig, the sleeve is the outside of the coax, and the end of the sleeve is a choke. He's written about it in English in CQ, 1999, Aug pg 22. The version in Norwegian is on the web at http://www.la2t.org/teknikk/vertikal2m.html.

I found an article from Microwave Journal about a very similar concept: http://www.ansoft.com/news/articles/04.05_MWJ.pdf. They use different kinds of choke, since they're at much higher frequencies. They report performance very similar to a dipole.

I don't care how people talk, as long as it is in civil fashion. (with
one exception)

But it strikes me odd that people who would *speak* such terms as
"73's", "QSL", and others, not to mention my all time favorite, "HI
HI", do not have much of an argument when they complain about a person
referring to S-units as "pounds".....

For cryin out loud, if its funny , LAUGH, don't say HI HI!

I read the title and thought "awesome!"

I agree with KD5SAK. This guy is trying to fit in. This is how ham radio works for most new licensees, and it doesn't matter if there's a CW test or not, if the exams are multiple choice or not. They want to pick up the mannerisms and operating practices of HAMS just as, when they were on CB, they used the mannerisms and operating practices of CB'ers.

Get on the air and operate and be a good example for the newly licensed. If they give you a signal report of "nine pounds" give them a "5 by 9"

Eventually the CB jargon will get replaced by ham jargon. Eventually the CB behavior will get replaced by ham behavior. Like building and analyzing antennas! And talking about them on the antenna newsgroups! And not going off topic! And being at fault for off topic posting even though I knew I should resist but it's such a tempting topic, and...

Newbie that I am(Tech, early 2003 and General, mid 2005) , I agree. And as far as Hi Hi goes, I always figured the early first users of the term probably meant for it to be read Hee Hee rather than High High. Again, as a newbie, I profess no great insight, I just express an opinon. I don't use either the 73 or the Hi Hi in QSOs or EMails, it strikes me as an affectation, but that may just be my newbie insecurity speaking.(g)

HI HI .... is, please forgive the reference to a hot topic, laughter when operating MORSE CODE [there I said it!!].

73, ---.. ...--, is BEST REGARDS in the same ridiculed transmission. mode.

If we are going to drop the talent for MORSE CODE we should be 100% logical and stop using acronyms that have meaning that are rooted in MORSE CODE such as:

QRL, QSO, CQ, QRM, QRN, QSB, QSY, QLF, QRS, 73, 88, HI, GD, GE, GM, TNX, DX, etc.

We should delete reference to RST on our confirmation cards [NOT QSL card]. We should delete GS and use DOLLARS.

Would someone start a petition to the ARRL that advocates that we should clean up our act?

Speaking of leading to a good paying career, if you're going to learn a skill, how about learning typing instead of Morse? Get on RTTY or PSK31 or one of the other digital modes and develop a useful, saleable skill. There isn't an employer in the world today (except possibly the ARRL) who would be impressed that you know Morse, but lots would like it if you could type.

Some interesting responses you have received. I think however something important has been missed.

On HF frequencies the received signal level is unimportant. What is important is the "largest difference" possible between the signal level and the noise level. In many cases improving an antenna tends to increase both noise and signal received by equal amounts amounts. (I should point out that this improvement does help transmitting though as at the other end you become a stronger signal relative to noise) A ground improvement in your case may reduce some losses but wont affect the S/N.

So ask yourself what you would do to increase the S/N ratio. A directive antenna may help, reducing local noise (like from generators etc) will too. I would guess that given you are mobile your options are limited. There have also been suggestions already about other antenna systems to try. If however RX S/N is the most important to you I would try a magloop for receive and a dipole or 1/4 wave GP for transmit!

Cheers Bob VK2YQA

Yes, indeed. Some good fashioned old amateur radio experimenting.

If I remember properly, it was a L O N G T I M E A G O, didn't
Katashi Nose, KH6IJ, learn to copy RTTY at the Hawaii station?

He could certainly crank CW. He spoke at a meeting of the local radio
club in the mid 1950s [Yankee Radio Club, Salem Massachusetts]

Gosh, if I remember properly, I'm getting OLD. Now if I can find my
driver's license I can figure out my birthday!

Cecil, W5DXP wrote:
"What Baud rate would be required for a human to copy RTTY by ear?"

The Baud rate is about twice the bandwidth according to Bell Labs`
Nyquist. Then Shannon, also of Bell Labs came along saying information
could be transferred much faster if the signal to noise were 30 dB or
better.

Using the standard Baudot or Teletypewriter code, about 8.000 words per
minute can be transmitted.

Operators who can copy Teletype by ear are likely to be rare indeed.

Best regards, Richard Harrison, KB5WZI

Dear fellow antenna lovers,
I have an extra 2m radio(IcomV-8000) in my living room. I use a
magnet-mount 5/8 wave
antenna on the radiator cover. I never had any problems reaching the
local club repeater about
15miles away. I only use it to keep "watch" over the repeater so to
speak,while downstairs
cooking,cleaning,etc. It always worked very well in that use.
Recently....NO MATTER where I position the mag. on the cover, I GET
a small signal that
"CAN'T" be squalched away !!! It's just white noise/static !!! IF I
move my handie-talike to around the same area(with-in 10-12 ft.) IT
ALSO reacts the same way !! WHAT COULD BE causing this PHENOM ???
I have changed the power supply.....nothing changes the problem. I
shut off the computor......the cable unit.....the T.V.,nothing seems to
STOP that
small signal,ONLY on 146.970mhz that it happens. ONLY that
signal...and on both 2m radios. Can't squalch it out....this is
driving me co-co !!! The antenna is right next to a picture
window....but that really doesn't matter 'cause it does it on the
Handie-talkie,same frequency,day or night. Can't figure this one
out.....any ideas what to do ??? please...

73's, Paladin

I've seen 2-meter spectrum noise from:

- Cable-TV leakage - worst is around 145.250, apparently due to the
video carrier leakage on Cable Channel 18.

- Multiple spurs generated by a switching power-supply regulator in
a Netgear wireless access point / IP router. The spurs were
apparently being radiated directly from the PC board, out through
the case - the power supply lead was adequately choked but this
didn't stop direct radiation. Other models of router (including
one from the same manufacturer) did not exhibit the problem.

- Noise radiated from telephone lines which have DSL networking
service enabled. Although the DSL signal is supposed to fall
entirely within the HF range, I believe that it has significant
harmonics up into the VHF which are not filtered out by the DSL
modems.

- Harmonic noise generated by a defective oscillator in an Ethernet
hub. This one was a doozie - it drifted through the 2-meter band
as temperature changed, and it caused horrendous squelch-tail
buzzing on several repeaters miles away when it drifted through
their input frequencies. Apparently it was radiating out through
the owner's Ethernet cables, and also getting back into the
building wiring through the power cord.

A device doesn't have to be complex to cause VHF QRM! Although it
didn't actually cause QRM, I did find another source of possible
interference recently when I tested and repaired a little two-tone
audio oscillator another ham had given me. It was a simple
battery-powered two-transistor oscillator based on a 1970s article in
QST. Due to its design (two simple twin-T oscillators using 2N2222
transistors) it was prone to break into a parasitic oscillation at one
point in the audio curve... it was putting out a nice 1 kHz audio
sinewave, with a VHF parasitic around 20 dB lower in amplitude,
wandering around from 130 to 160 MHz. One ferrite bead on the base
lead of each of the two transistors completely cured the problem.

Other people have reported nasty-noisy signals from oscillations in
TV-antenna preamplifiers... these have caused interference to 2-meter
ham operators, aviation band, and even to GPS (see the page at
http://www.gpsworld.com/gpsworld/article/articleDetail.jsp?id=43404
for a summary).

> Can't figure this one
>out.....any ideas what to do ??? please...

Do the "turn off and unplug" bit again, but go even further. For
starters, try turning off the main breaker for your whole
house/apartment. This will be a very clear way of telling you whether
the noise source is internal or external.

If it's internal to your home, turn the breaker back on and then start
unplugging every single device in the house (no matter how apparently
harmless) one at a time until the QRM goes away.

If it's external, go hunting. Get yourself a 2-meter directional beam
antenna (or make one - Google for "tape measure Yagi") and start
DF'ing.

If you track it to a neighbor's house, introduce yourself politely and
explain the problem and try to enlist their cooperation in finding the
source of the emission.

See if you can find someone in your area who has an RF spectrum
analyzer good up to 150 MHz or so. It can be very instructive to look
at the whole 2-meter band, and see whether you're seeing a single
carrier, broadband noise, or multiple narrowband spurs. A spectrum
analyzer, hooked to a portable Yagi via a 20' coax, makes a *very*
nice "characterize and locate" tool.

When I helped my city's RACES EC locate the source of some nasty
2-meter RFI which was desquelching his radios and interfering with his
ability to receive simplex, it took about 10 minutes with an
analyzer-and-Yagi combination for me to be able to say "Well, it's
your next-door neighbor's condo, upstairs, in the back, polarized at
around 45 degrees from the vertical. and is multiple spurs at about
50 kHz separation."

The bad news is that on many 2-meter frequencies, there's so much hash
and garbage in urban areas that it's necessary in practice to turn on
a receiver's tone-squelch, and force the receiver to remain muted
until it hear's a repeaters output CTCSS tone. If your repeater
doesn't put tone on its output, then this won't work, alas.

I suppose there are many "affectations" like OM, or Old Man and FB, or
Fine Business. Just to add to the list.

All appear to be derived from CW operations.

I think they're great.

Nothing, especially jargon, is unchanging. I suspect some CB jargon could bleed over. I must say that "nine pounds" won't be used by me, however.

RHF,
My point was ...this time the FCC is NOT *eliminating* nor *Outlawing CW.
(as far as we know)
Spark *did* suck, but even so there were those that hated CW.

ARRL threw principle out the window when they caved in to the demands of
the Lambda Amateur Radio Club (LARC). It was a sad day for me indeed when
I opened my beloved QST magazine and there on the pages were photos of
queers on a Tropical DXpedition, and in living color no less. The ARRL
wanted us to embrace a sick perverted lifestyle and be one big happy
family. To me, it was the spark that signaled the death of a once proud
organization, and it turned liberal.

I chalked it up to a new op happy about working a new state. I remember having the same feelings he had when I was first licensed. I worked all states on CW before I ever made a voice contact because Novices weren't allowed phone priviledges when I got licensed. It was a blast and helped my code speed so I could upgrade to general with little effort.

My problem, a lot of new ops aren't leaving old CB operating practices behind. That is what will destroy ham radio, The CB like behavior.

It must be human nature, when you get something for nothing, you don't appreciate it as much, or try to take care of it the same as something you had to work for. That's why dumbing down ham tests is bad. Having a license doesn't mean anything.

I'll add GPS receivers to that list. I've seen some pretty big spurs on 2 meters from a couple of units I've owned. But it's not the sort of thing that's usually on constantly in a residential area.

Yes, again I agree. I never used such terms when I was a CBer, all those years ago. I also didn't attempt the "L'il Abner" language distortions that became prevalent on that "band". Even in those days communication was the goal for me and my main hobby efforts involved antenna building. Even today, though Ham transceiver technology has far outstripped any possible homebrew efforts I might wish to try, I can still fiddle about with antennas and do. Aside from mobile antennas, the only "storebought" antenna I have is a Hustler 5BTV vertical. They're very popular among my local Ham club members, probably because we have such good local soil condutivity and they serve well ground mounted without radials.

<< I once made a J-pole from 300-ohm twinlead and tweaked it until it worked
<< OK while hanging from the ceiling, but when I moved it over next to a
<< wood-framed picture window (hung it from the window casing), the SWR went
<< to pot. Did I do something wrong?

<What kind of metal was behind the window frame?

The house was old enuf that I'm sure it was made of wood, and
since it was a PICTURE window, there were no sash weights, either.

So the question remains: are J-poles sensitive to nearby materials?

>together at each end.
>....[snip]....

Someone mentioned a bowtie, but with just a bit of not-looking-carefully-enuf, it might be a three-wire folded dipole?

IIRC, put a one-wire (each side) dipole high enuf and its impedance is about 72 ohms.

Use two wires and get 2x2x72 => 288 ohms (which everyone says matches 300-ohm line).

Use three wires and get 3x3x72 => about 650 ohms, which might be well fed with open-wire feeders?

I also recall folded dipoles are somewhat more broad-band than single-wire dipoles. (Because they are effectively "thicker"?)

Brings up another question: can folded-dipoles be good multi-band antennas?

In the heyday of RTTY as I remember it, you could put two 8-channel muxes
(85 Hz AFSK per channel) into one SSB transmitter. One of the muxes was
at baseband and the other was heterodyned up by about 1800 KHz and
"stacked" on top. Nyquist might predict 8,000 wpm capability but I never
saw hardware that approached that number. With QPSK, I dunno ...

>

I can recognize a test tape of RY's and I can hear the periodic <CR> <CR>
<LF>
but I can't recognize any of the alphabet, even at 60 WPM (45 baud)

I have it a little bit here and (can't recall) it might be the one I chased
last year. I went out for a one-on-one T-hunt and ended up back home,
pointing at my own garage door opener. It's proably LO radiation.

I picked it up in multiple locations, which was a puzzle at first. But now
I know which houses have a Genie Garage Door Opener ;-)

I had a similar problem. I don't remember the frequency it covered,
but it was one of the local repeaters, I think it was 145.41. It came
up slowly stronger for a few days, and then I found it. it was a
signal being transmitted by dad's cordless phone base through the
power line so it covered the half of the house that circuit was on.
Once I found it, I had the phone replaced.

What I don't get is why we are forced to see
homosexuality in areas that have nothing to do with sex, such as the example
you mentioned.

First, go to http://www.antennaweb.org/aw/Address.aspx and find out where
your stations are, and how big an antenna you need.
www.warrenelectronics.com sells all the stuff you will need. If you operate
any HF or VHF, you might want to get a UHF only mast mounted amplifier, to
keep TVI out. I have the ChannelMaster 7775, which works well. Ditch the
RG59, and get decent RG6 coax.

>So the question remains: are J-poles sensitive to nearby materials?

yes, and also, RF doesn't always saturate an area.

The wire in the j-pole is affected by the insulating material the twin lead is made from. Different types have different dimensions for the j-pole lengths.

Though it doesn't make sense sometimes, moving an antenna near a wall may cause a negative effect. I have that problem at my kids house. They are hams and I setup a hook in the ceiling to hang a pole. It worked, but their mom didn't want it hanging so far from the wall and moved it against the wall. It doesn't work. So we found a compromise spot near another wall, a corner actually. It works but it is leaning at about 20 degrees coming from the corner.

There is also a problem of RF holes. Mobile operators and HT or portable operators experience them the most. It is the cause of picket-fencing. The mobile moves from a hot spot to a not-so-hot spot. A portable rig can usually find the hot spot or the dead spot easily. I can hit the local repeater from inside my room with low power on my ht. outside about three feet away, I can't hit it on high power. It is further from the wall there.

Good luck
Buck

>So the question remains: are J-poles sensitive to nearby materials?

That depends on the materials. Conductive, or lossy-dielectric materials seem to have a significant effect especially when located near the high-impedance points.

When I built a ladder-line J-pole and hung it next to my house's outside wall, it de-tuned quite badly. Its performance stank so badly that I could barely reach a nearby repeater.

When I hung it by an inside wall, it was not de-tuned enough to affect the radio's performance appreciably (I didn't have an MFJ meter at the time and so don't know the actual degree of de-tuning). I was able to hit the repeater quite well even though the antenna was further inside the house.

The first (outside) wall was stucco... with embedded chicken wire. The second (inner) wall was drywall and lumber.

I suspect that exterior brick, or stone, or wet wood, would fall somewhere in between the two in terms of de-tuning potential.

My guess is that the classic J-pole may be somewhat more vulnerable to being de-tuned by nearby materials than a center-fed half-wave radiator. The quarter-wave matching section is often fairly critical of adjustment - I've read reports that even small changes in the configuration of the upper potion of the matching section (e.g. material near the open end of the stub, or changes in the spacing) can cause some fairly large changes in the J-pole's feedpoint impedance. Standard J-pole antennas seem to work most stably when built of rigid materials and mounted "in the clear".

I haven't read any reports of actual experiments which attempted to quantify the tuning stability of the classic J-pole, compared with variants like the Arrow (a.k.a. Cebik's nontypical design), the open-sleeve, and the sperrtopf coaxial design, or compared with a center-fed dipole or other varieties of halfwave radiator. It'd be an interesting study to try to put together.

My experience at my kids' place is that it has the same effect on the vertical dipole as it does with the jpole. I have a dipole I created by using wire inside a cpvc pipe. The coax was rolled up to form the choke balun. The dipole antenna has the same problem with hitting the local repeaters as the jpole did. In the same places, the two antennas had such similar effects that I could literally not tell a difference either in audio or signal strength as displayed by the radio. SUper J-Poles, on the other hand, perform much better than either the j-pole or the vertical dipole.

Roy Lewallen <w7el@eznec.com> wrote in news:126269t8n8f5da4
@corp.supernews.com:

You're probably the right person to ask this. Do you know or have any idea what the resistance per foot is of the shield on LMR400 at 3.75mhz? I made a 55-inch diameter loop out of the stuff, using the inner conductor's capacity to resonate it and coupling with a gimmick wound on the outside out of 4-wire flat phone wire. Works pretty good, actually. I think it beats out my hamstick by a couple of db, but can't really be all that sure.

Also made a 2 turn job for 160 (it's smaller than the 75m one). It plays, too, but I'm sure it's not really very efficient. Still, any antenna that works is better than none at all, and with a 2nd story balcony as the only space to erect them in (or else indoors), I'm experimenting.

I may try something more ambitious in 3/4 inch soft-drawn copper pipe, about 6 feet in diameter. That should get me another 3 or 4 db, I think.

Still, these coax loops seem to be working amazingly well for something so simple and relatively inexpensive.

>What is one behavior on our ham bands that might or could make you loose
>interest in ham radio and leave if you heard it or if it became previlent?

None. I have fairly thick skin, and I'm rarely bothered by anything
that
happens on the air. I do have a VFO ya know... IE: tuning knob for all
you without an EE... But like I say, I'm pretty bored lately, I don't
get
on the air near as much as I used to. The boredom has nothing to
do with the people on the air. It's from farting with the same basic
stuff
since I was in jr hi school... I don't get much thrill anymore.. Only
about
3 clicks above talking on a telephone. Which I hate btw... Ham radio
at the house is too easy. No challenge anymore.. I turn it on, and yak.

Wow...
If it wasn't for mobile/portable operating I would be about radio dead.
At least there is still some challenge in that area... IE: trying to
put out
a decent signal with shrimpy antennas, low power, etc..
Yea, I've tried all the digi crap too, before I get 90 people telling
me to
get with the modern techniques....PSK31, SSTV, etc, etc, ad nausium..
I'll do it for two weeks, and then the boredom sets in... I kinda got
into
SSTV, but PSK31 bores me to tears... Did I say I generally hate to
type...

>And does it seem like it's going that direction?

I see no difference from what it's been the last 20 years or so, except
there
are far fewer CW ops on the air lately. I tuned 40m CW the other night,
and
didn't hear a single QSO... And I'm talking the lower CW section, not
the
novice band.. But do I whine? Nope...Times is a changing, and there is
not much I can do about it. The argument that CW weeds all non hackers
is total BS... All it weeds out are the CW lazy, not the troublemakers.
A dedicated troublemaker will pass any tests needed if that's what it
takes to stir it. You should have heard 75m in the early -mid 80's...

All had to pass code tests in that period. 75m is actually cleaner
now,
than it was then. Mainly due to Hollingsworth cracking his whip a few
years ago.

Even more amazing is that no matter who starts the thread about CW, the
same group of people will post the same tired old reasons about why CW
is still a useful screening tool for prospective hams and how CW is
still an important way to communicate. And they do not want to hear
about the world as it really is in the 21st century.

If I had the time at the house, I would have invested more time and $$$ in
the shack that what I did in my service truck.

> Wow...
> If it wasn't for mobile/portable operating I would be about radio dead.

For the most part, I am only able to get on the air mobile from mid march
until after the first frost. I am a heating and a/c contractor in south
Mississippi....8am - 9pm work days, 5+ days a week doesn't leave much time
for anything else.

> At least there is still some challenge in that area... IE: trying to
> put out
> a decent signal with shrimpy antennas, low power, etc..

Not too much of a problem with enough money.... When I am on the road
between calls, if I want to talk, I am going to talk, even though most of
the time I am listening. Like I said earlier... I have more invested in the
mobile station in my service truck than I have in the shack.

> Yea, I've tried all the digi crap too, before I get 90 people telling

I spend too much time on the 'puter already, and FWIW, I was on packet in
'84 with a C-64, and a homebrew modem, and customized my own software for
it.

I have been active recently with teaching a class for folks to get their
licenses and part of it is CW. Being here in south Mississippi and only
about 60 miles from the gulf coast, we are very aware of the communications
limitations and what works an what doesn't when the lights go out. CW is
only another weapon in our arsonal of communications tools......keep in mind
that not much works when there is *NO* infrastrucure left intact.

Boy O' boy....it's good to get a little humor about this ! I HATE TO
"not" UNDERSTAND a problem like this. The New England Spectrum
Management Group has their problems more important than mine. After
all, I DO have a "proper",outside 2m beam set up
and on that antenna there are "no issues". I need to use a VFO on 2m's
to see how wide of a signal I'm recieving. Maybe my RF-
current meter or the MFJ analyzer can aid me on my "indoor fox hunt".

>

My limited experience with three J-Poles indicates that they are very sensitive to nearby materials. I tried tuning in my shop which is fairly cluttered and in the basement of a stucco finished townhouse. I used thin rope to hang the J-Poles from an overhead floor joist. Changing the location by only several inches changed the SWR. I found a spot about four feet from the nearest object which gave the lowest SWR. A ladder line J-pole was still very difficult to tune and it changed significantly when it was moved to the attic. A copper J-Pole was easier to tune but it also changed when it was moved to the attic. The Arrow end fed was "store bought" so I didn't make any adjustments in the basement. It had a reasonable SWR in the basement and it didn't change when it was moved to the attic.

I did some more tuning of the copper J-Pole on my deck. SWR changed with location, even though the deck is fairly open. The best SWR was with the J-Pole in a 5 gallon pickle crock sitting near the center of the deck.

For isolated characters, a good ear could probably differentiate them
with 22 millisecond and 20 millisecond bit times (45.5? and 50 Baud).
I had a friend who said his uncle could do that.

But if the characters ran together, especially with a 1 or 2 bit stop
time, your brain would have no way to seperate them. Neither can some
simple hardware decoders.

On Wed, 10 May 2006 09:05:54 GMT, Dave Oldridge
<doldridg@leavethisoutshaw.ca> wrote:

>what the resistance per foot is of the shield on LMR400 at 3.75mhz?

Hi Dave,

With the aid of an Ohmmeter, you should be able to determine that
without need for theory or books. Unless, that is, you simply try to
determine it for one foot's length where the resistance is bound to be
so small as to be buried in the resolution of the meter's display.

If we were to simply assign a total resistance of 0.1 Ohm, then from
what follows you would find yourself in serious trouble. You should
be shooting for at least one tenth of that value IN TOTAL. The
practical reality of this is that your connections may have more
resistance than the bulk cable. Further, at this level of resistance,
you need to make four lead (Kelvin) measurements.

>I made a 55-inch diameter loop out of the stuff,

More to the matter would be the radiation resistance of this in the
80M band where you use it. This sets up the necessity of knowing that
LMR's resistance (much less the TOTAL). The radiation resistance of
such a small loop runs 0.002 Ohms.

If you used the same size loop at 160M, that figures out to 112 ï¿½Ohms.
However, you use something smaller, and thus that figure is following
down further, faster.

>I may try something more ambitious in 3/4 inch soft-drawn copper pipe,
>about 6 feet in diameter. That should get me another 3 or 4 db, I think.

Then you would find that radiation resistance now turns out to roughly
double the former values.

>Still, these coax loops seem to be working amazingly well for something so
>simple and relatively inexpensive.

This observation (not really explained by you as to what constitutes
"amazingly well") can be a product of two realities:
1. You don't actually need much power to communicate;
2. Tuning up has been leveraged by a lot of loss.

Source record: 59865

LMR400 outer conductor should be a bit less than 10 milliohms per foot
at 4MHz.

Rule of thumb: for copper, assuming thickness at least a couple of
skin depths, RF resistance in ohms per thousand feet is about
sqrt(freq(MHz))/(diameter(inches)). Aluminum will run 25% more or so.
I've assumed the aluminum foil shield of the LMR400 is at least 3 mils
thick, and I've neglected the overbraid.

Cheers,
Tom

2225. Double Windoms

Newsgroup: rec.radio.amateur.antenna

Message-ID: <1147285216.336206.77370@g10g2000cwb.googlegroups.com>
Source record: 59866

I would like to hear about experiences and comments on double windom antennas.

So far there are three designs that I have found reference to:
A Double Windom Antenna for Eight Bands by Hubert Scholle, DJ7SH, and Rolf Steins, DL1BBC, cq-DL September 1983.
A Double Windom Antenna for Nine Bands by Hubert Scholle DJ7SH, cq-DL July 1984.
The Off-Centre-Fed Dipole Revisited: A Broadband Multiband Antenna. by John Belrose, VE2CV, and Peter Bouliane, VE3KLO. QST August 1990.

The Belrose and Bouliane article includes a translation of the two cq-DL references above and is available to ARRL members at http://www.arrl.org/members-only/tis/info/pdf/9008028.pdf.

Are there any other published designs or articles?

Belrose and Bouliane advocate the use of balanced feed line constructed from dual parallel RG-62A or RG-63 coaxial cable. What is the advantage of using the coaxial cable instead of 300 ohm twin lead or 300 ohm ladder line?

Darrell Bellerive

Message-ID: <1147295279.139842.67000@q12g2000cwa.googlegroups.com>
Source record: 59869

All,

If you were given a phased array of 30 elements, which provided a formed beam of 3.1dB/K, and you were required to determine the dB/K of a single element from that 30, how would you do it? Would it be 3.1-10*LOG10(30)?

Also, would the net combiner gain, including beamforming losses, plus the single element dB/K be equal to the 3.1dB/K?

Thanks in advance.

Bobby.

> wave. Traditionally, it's called coaxial sleeve antenna.

OK, perhaps I missed the full reference. I read "end fed dipole" and
went from that. The sleeve dipole is still a dipole (I have one for 2M) and
is still center fed. The lower half (lower, hollow, quarter wave with the
t-line passing through it) is viewed as a "choke" by some as well. You can
do some mental games with your models and take the sleve and spread it out
into a cone, then a plane and say that the sleeve dipole is sort of a
configuration of a 1/4 wave ground plane of a different color. Various
analogies are possible depending on your particular way of understanding the
basics. This is what I call "mental models".

That Microwave article is showing different concepts, but along the same
line of the "non-sleve" antenna. you can take a coax, strip off 1/4 wave of
outer to leave 1/4 wave on inner projecting out the end, then do various
things with gaps in the the shield (whthout adding a classical sleeve) and
get radiation and minimize coax radiation (except were you want it, or
perhaps more correctly, where it helps it to be a better antenna (for
whatever charasteristic you want in the first place).).

Rolf Brevig's choke is something I don't think I've seen before, but I
understand the concept. I can't tell, but I suspect it is common "1/4 wave
stub", no?

Jon,
I also just realized that the choke is very similar to the Microwave article's concept of simply opening the shield. I think that was your point.

Hi Bobby,

Gain is not proportioned across elements even though there is a
correlation between their count and the total gain.

dB/K is for noise temperature, not element count. Your equation
>3.1-10*LOG10(30)?
suggests a temperature of 30ï¿½ absolute, not 30 elements.

I just passed my tech exam and am looking
forward to the CW test. It certainly exercises
a part of my brain that seems to need that
kind of excercise. I'm glad it's still a requirement.
It all seems to balance out.

At the same time the price of gasoline has gone up, the minimum wage has gone up, the stock market has gone up but in just about all areas of society mutual respect and courtesy have gone down.

I think it has very little if anything at all to do with Morse code.

When I was born (1-10-33) there were approximately 130,000,000 Americans. I think we are approaching 300,000,000 now. I'm still relatively polite, I think that may be why I get so many funny looks when I speak to folks. Poor as we were, I think I liked the 30s and early 40s a whole lot better. Main thing I've noticed about the more recent citizens Is that there have never been so many with such high self esteem and so little reason for it. (G) I'm a relatively recently licensed Ham (Tech-2002, Gen'l-2005) Had no real interest in CW but realized I had to pass the test to advance beyond the no-code Tech level (Besides, I figgered actually having passed even the elementary 5 WPM CW test would eventually be a prideful thing.)

I'm a couple decades younger than you (my mother was born in '33), but I
have sure seen a massive change in societal attitudes since I was young.
Used to be that people understood the concept of earning what they get out
of life, now everyone seems to think they're entitled to anything they want
for free. Kind of sad, really.

Yessum, I agree. I always hated to work, but I always understood that it was
something I had to do.
I was a high school dropout, but after I got out of the Army I picked up two
college degrees. I never really amounted to much, but did pretty well for a
dropout, even taught Industrial Arts in a Dallas Junior High
School for eleven years. Finished my working years as a Design Drafter (CAD)
for Halliburton.

OK, thanks. That pretty much agrees with my experience.

I'm not trying to compare apples and fir trees here, just apples and oranges. The antenna I'm trying to better is a hamstick whip and this coax loop seems to beat it by about 1 or 2 db (I have them on an AB switch that gives me the tuned antennas at the touch of a button). With the whip horizontal and the loop vertical, both have NVIS performance at high angles that is quite similar, but the loop is less noisy on receive and has a tiny bit more signal strength on actual NVIS signals.

As I said, I'm encouraged enough to go ahead now and try something in copper that should have a lot less losses. If I can get efficiency up into the 10% range, then it's a real winner over a mobile whip.

The coax antenna is certainly a good little field antenna for quick deployment. Can be carried in the trunk of a car along with a radio and its feedline. And can be hung out with only string.

Sure, if I had 40 acres and lots of cash, then a four-square and a rhombic would be the way to go (Canadian hams are clumped along the border, making a rhombic practical when you're at either end).

So... close to 0.140 ohms loss restance for the loop conductor, and if the loop is resonated by the o/c stub which presents an impedance of around 0.14+j116, and taking Richard's estimate of Rr at 0.002, the the efficiency of the main loop (ignoring coupling loop / circuits) is about 0.002/(0.14+0.14+0.002), less than 1%, or about 21dB of loss.

It seems that the convenience of the TL loop / capacitor comes at a significance expense.

Owen

What is sad is that in California they deny the Boy Scouts public park access, but it is OK for gays to have public sex in the same parks without fear of being arrested.

That, sir is about to change:

I wondered about the effect of mast material, so I took a freshly built
j-pole and mounted it in the clear. I noted the XMIT reflected power (low)
and moved a ten-foot piece of galvanized steel mast around the antenna, I
found I had to get within about an inch to see the reflected power increase.

Next, I found a repeater with nearly continuous chatter and connected the
j-pole through an attenuator to my radio. I set the attenuator so the
received audio was very noisy -- another dB or two and the conversation was
unreadable. That same piece of mast material had essentially the same
effect: had to get really close to louse up the antenna's performance.

That said, if I take a j-pole and walk around with it, periodically
measuring the reflected power, I will see physical locations where it bumps
up. That's probably not detuning; it's probably reflected power off a wall
or fence, which could be what's happening in the OP's attic. (Navy ship
radars' reflected power monitors will "bump up" every time the antenna
rotates past the mast or some other bit of ship's structure.)

Is this great science? No. Is it worth noting? I hope so.

Took a short look at your data. Did not have any (GN) difficulties running it. (btw the negative GN value is used when running the model using a freq-loop/sweep). However it showed up you model is largely unreliable due to the large segment length differences at the end of you 'dipole'. When running an average-gain test you will also notice a value of 0.35, indicating a largely unreliable model.

Arie.

Thanks.

I'm trying out the shareware program "nucode"
right now. Is this a recommeded way to learn CW?
```

My long term plan is also to pass the General exam,
then build my own HF CW receiver, and then later
try transmitting low power to see how far I can
go on an empty tank.

A 1/4 wave stub would work better, but be less simple to
fabricate. This design is trivial. It's just a coiled length of coax.

> I also just realized that the choke is very similar to the Microwave
> article's concept of simply opening the shield. I think that was your
> point.

That was my point. But I now see that we're putting it at a high
impedence point, so the isolation is going to be far from perfect.

Anyway, my *real* point was that this was a useful antenna. Carry one
rolled up in your pocket and hang it from a tree to extend the range
of your HT. Cut one for 156.8 MHz and keep on your sailboat in case
you're dismasted. Etc.

SIG < zero is new to me, but I see it is mentioned in the NEC users
manual. Segmenting tags 1, 2, & 3 at 201 fixes the Average
gain test. Not sure if you can apply segment length tapering to speed up
the program.

Interesting design: VSWR < 2.5:1 over 1 MHz, Zin nominal 600 ohms,
fr ~ 6.8 MHz.

Maybe reflected power off of nearby objects is the cause of poor
performance of my J-Pole in the basement shop. And the attic has the
roof overhead and many, many cross braces, typical of pre-fab trusses.
Anyway, I am satisfied with the Arrow end fed antenna in the attic.
But, I am disappointed with my home made J-Poles. Maybe I will try a
little SO239 1/4 wave, just to see if there is any difference.

Thanks for the help, jimbo

I'm wondering if you are using a common mode choke? Also what type of
mast are you using to support the antenna?

I have tried with and without a coax loop, 5 turns about 6 inches in
diameter. I couldn't see any difference. I use a 1/8 inch diameter
rope to hang the J-Pole from a joist in the basement or from a roof
rafter in the attic.

Let's use proper nomenclature. There is little danger of CW going away. What is going away is Morse Code - replaced by more efficient ways of comunication. We're always asked "What would you do is the only way you could communicate was to turn your transmitter on and off?". Simple! I'd use Tap Code - you know the "CW" with only dots, no dashes - the one used by banging on pipes, the one anybody can use without tons of practice. Arrange the alphabet in a 5 x 5 matrix leaving out K (use 'c' instead). Each letter is addressed by its position in the matrix: a = 1,1; b = 1,2 .... f = 2,1 and so on. These become your "dits" or bangs or flashes or blinks as appropriate. I'm amazed at how few know this.

why? or better what makes it higher?

to do so implies that it is accepted that there is soething worng
inherantly with saying or typing "shit" when "shit' is what you mean.

given that words like "shit" "fuck" have an impact beyond their
equivelanets feces, and fornication, why ot use them

the only that does is foisting a morality thatI don't accept

agree the word I mentioned and other are over used but that is a only a
problem in that it lessens their impact not that it is worng

Your choice of language clearly identifies your value system.

The subject you passionately defend is considered immoral by 90+ % of the people in the world, and ALL the world's established religions.

A multicultural society will condone your language and lifestyle; and, YES, you must condone their 'straight' lifestyles. Any right you claim for yourself you must also respect in others with whom you disagree.

Finally, this thread is so far off subject that it deserves a quick referral to the circular file.

I did a bit of experimenting along this line and found that any fixed antenna hung from a tree was a poor way to extend range. As you probably know, multipath propagation causes dead spots every few cm -- the cause of "picket fencing" when mobile -- when you're in a marginal area where a better antenna would help. Any fixed antenna is fairly likely to end up in one of those dead spots. And additional gain due to height is likely to be largely canceled by feedline loss unless you carry along some large diameter coax.

What I've found to be the best VHF antenna for portable use in marginal conditions is a telescoping half wave antenna like the AEA "Hot Rod" or various imitators like the MFJ. They radiate as well as a J Pole, but have the advantage that you can move them around to find a "sweet spot".

A single choke blocks conducted common mode current. But a J pole (and ground plane, for that matter) can also have considerable common mode current due to coupling between the antenna and feedline, which can distort the pattern and reduce the gain at the horizon. This can actually be made worse by a choke in some cases. Two chokes, about a quarter wave apart, are necessary to reliably reduce the coupled current. The amount of conducted and coupled current you have without chokes depend on the feedline length and orientation, so it can be small in some installations and large in others. I suspect that's one reason why people report such widely varying degrees of success with this antenna.

All you guys posting to this thread do not know anything about Usenet.

All this crap is being cross posted to newsgroups where there should
be no interest in this bickering, childish behavior.

Before you do any follow ups to this message, right before you hit
your send button, look at what newsgroups you are posting to. Delete
(do you know how to use your delete key?) all the newsgroups except
rec.radio.amateur.misc. then the antenna newsgroup and the equipment
newsgroup etc. will not be seeing the posts which are IRRELEVANT.
So if you like this bullshit bickering stuff go on over to
rec.radio.amateur.misc and you will see there are lots and lots of
them to entertain you all night long. You can call all of the posters
there names to your hearts content.

Hi everybody! I want to mount a dipole FM antenna on top of a three story building. My transmitter will be located in a room in the bottom floor. Has anyone have experience in this?

I know that I will get some signal attenuation with that long of a coaxial cable (100 meters). If my cable has a characteristic impedance of 50 ohms (matching the output impedance of the transmitter), will it adversely affect my transmission?

I was reading my electromagnetics book and it mentions that depending on transmission line length the cable might look like an inductor or capacitor.

What other factors should I take into account my calculations for the effect of the cable length on the system?

My current setup includes a 100w low power fm transmitter being fed by a computer running some school audio programs. Thnx!

>coaxial cable (100 meters). If my cable has a characteristic impedance
>of 50 ohms (matching the output impedance of the transmitter), will it
>adversely affect my transmission?

It may, depending on the type of cable you use. Thin-gauge coax cable
(e.g. RG-58) will cause significant attenuation over that long a
run, at those frequencies. Heavier-gauge cable would have lower loss.
I wouldn't use anything less than a high-quality RG-8-type cable (e.g.
LMR400), and would seriously consider using a hardline (e.g. cable-TV
aluminum-jacket).

>I was reading my electromagnetics book and it mentions that depending
>on transmission line length the cable might look like an inductor or

Umm, the possiblity that you might end up having your equipment seized,
and/or be hit with a really heavy fine, if you don't do all of the
paperwork properly?

> my calculations for the
>effect of the cable length on the system?
>
>My current setup includes a 100w low power fm transmitter being fed by
>a computer running some school audio programs. Thnx!

Are you intending to operate a legitimately-licensed educational LPFM
(low-power FM) station on behalf of your school? If so, whomever
filed your LPFM application to get an FCC construction permit ought to
have done a lot of the necessary design work and calculations at that
time.

If you haven't received an LPFM license from the FCC (new applications
haven't been accepted since 2003, apparently, and such licenses aren't
available to private individuals), I'd advise against attempting this
sort of installation. The FCC occasionally raids "pirate" FM
stations (those operating unlicensed), seizing the equipment and
citing the owners/operators. The financial penalties for operating an
unlicensed FM station could be really severe.

I don't think there's any chance at all that a "100w low power" FM
transmitter could reasonably be used in a way which would qualify it
under the FCC Part 15 limits for field strength (250 microvolts per
meter, measured at a distance of 3 meters from the antenna) if you
feed that much power into a dipole antenna.

Source record: 59725

>From what I have read there seem to be two common types of choke baluns employed at 146 MHz, the coiled coax balun and the W2DU type with ferrite beads over the coax. Looks like other types of baluns such as the sleeve balun or a Guanella toroidal balun could also be used.

Other than the obvious restrictions imposed by physical mounting arrangements, what are the advantages and disadvantages of each type.

There seems to be considerable variation in the design of coiled coax baluns, with most designers advocating a few turns of coax with a diameter of 3 to 8 inches. One designer was convinced that anything over 3/4 of an inch would not be functional at VHF frequencies. Others maintain that the coil of coax should be wound on a core keeping the turns aligned, while others simply coil the coax up and tape it together. Some recommend one coax width of air between turns.

With regard to ferrite beads on the coax type of balun, how many ferrite beads of what type are most effective? Some advocate that another set of ferrite beads be placed at a point below the feedpoint.

Seems there is lots of latitude in construction of these types of baluns. Are they really this forgiving, or are there a lot of less than full effective balun designs?

I'm trying to decide what is the best option for me, and am confused at all the variations.

I forgot to mention that the radio station is not based under FCC jurisdictions. It is used for a none government / non-profit organization in another country.

Ah, OK. That clarifies things quite a bit. Just make sure that you
cover your bases with the other government's authorities... some of
them may be as humorless as the FCC.

First thing I'd do is suggest that you take a look at coaxial-cable
attenuation figures. http://users.erols.com/rfc/attenrat.htm has a nice
table which shows the attenuation in dB per 100' of cable, at various
frequencies. For a first approximation I'd suggest using the "100
MHz" column.

As you'll see, 100 feet of RG-58 coax has an attenuation of 4.5 - 5 dB
at 100 MHz. That means that almost 3/4 of the power is lost as heat
in the cable - only about a third of the power makes it up to the
antenna. If you *really* need a 100-meter run of cable, triple that
loss... only a single-digit percentage of your power will reach the
antenna.

Good RG-8-size cable is better. LMR-400 loses 1.2 dB per 100', which
means that you'd get almost half of your transmitter power up to an
antenna 100 meters away. LMR-600 is even better, at 0.8 dB per 100' -
you'd have more than half of your power left. Some of the really
fancy/thick/expensive hardline cables are even better - LDF5-50A
would have just a hair more than 1 dB of total loss in 100 meters,
which would really be negligible.

This suggests two things:

- It'd pay big rewards to see if you can route the cable as directly as
possible. I can't see any good reason to run 100 meters of cable
to go up a "three story" building!

- Don't use cheap, thin cable... don't use anything less than RG-8.

As I mentioned before, aluminum-jacketed cable-TV "hardline" may be a
choice to consider. It's often available in useful lengths, either
for free or for scrap value, from cable-TV operators - they buy and
install it in large quantities and often don't have a use for the
"cut-off" pieces at the end of the spool (and such "cut-off" remnants
may be 100' or more in length).

This sort of cable has a 75-ohm characteristic impedance. It might
actually provide a better match to a dipole antenna than 50-ohm cable
would (depending on the antenna type and mounting arrangement). The
modest SWR at the transmitter might or might not be an issue... if it
is, a simple two-component (one-inductor, one-capacitor) "L" matching
network can allow the transmitter to "see" a 50-ohm load even though
the antenna and coax are both 75-ohm.

==========
That the cable will look like an inductance or capacitor is a load of nonsense. Change the books you've been reading. Don't read the comics.

For minimum loss in the cable the input impedance of the antenna should be approximately the same as the cable impedance.

If the cable loss is 3dB then half of the transmitter power will be lost in the cable. Check the cable manufacturer's specification for actual loss per unit of length.

Very approximately, if the diameter of the coaxial cable is doubled then the loss in the cable, in dB, will be halved.

On the other hand, if 3/4 of the Tx power is lost in the cable, then depending on the distance to the customers' receivers, it might not matter very much. Everything depends on the required service area of the transmitting station. There's not much point in buying expensive cable to radiate 100 watts if 25 watts with cheap nasty stuff is good enough.

Think in terms of your bank balance.

I don't see how this is any more efficient (indeed, it appears to be
less efficient) than CW-Morse code. My understanding is that Morse
wisely used the least complicated sequences for the most commonly used
letters. I think this is also true of PSK31, but I could be wrong.

Consider the letter "E": a single "dit" in Morse, but it becomes
one "tap" followed by 5 "taps" in the above scheme. None too efficient,
it seems to me.

Is there any optimum height for a 3ft dia magloop, or is it dependent on frequency??.

I have mine planted in the lawn with the top about 6ft from the ground (on a rotator!)
and was curious whether to work it against ground or put it at the top of the tower,
or have i completely lost the plot???, Heh heh........

Surprising how cheaply a magloop can be built for and after 12 months it still works well!!.

Thanks.....

What band is yours on? I have a 55-inch diameter coax loop that I'm using on 75, but I'm seriously thinking of working up a multiband design in soft-drawn 3/4" copper pipe. It would be six feet in diameter (mainly due to space considerations).

==========
Lee,

There is no optimum height for a magloop.

Loss induced in the ground reduces as height above ground increases.

When the height of the bottom of the loop is more than the loop
diameter, loss in the ground can be considered negligible.

This is modelled in program MAGLOOP4 which can be downloaded from the
website below and run immediately.

==========
Dave,

Magloops with copper pipes are the most efficient of all small
antennas.

They should be rotateable through about 45 degrees.

Changing from coax loop to 3/4" or 1" copper pipe loop will be a
considerable improvement on both transmit and receive. Especially if
it is not too low above ground and is not in a cluttered environment.
The idea is to keep ground loss less than conductor loss.

For multi-band operation you will be best with a motor-driven vaccuum tuning capacitor. With a 1000pF capacitor and a small loop the 160, 80 and 40m bands can be covered. It depends on the minimum capacitor setting and loop perimeter.

There is no noticeable difference between aluminium alloy and copper pipe. Aluminium alloy is lighter in weight and stands up to the weather better but is more difficult to bend.

A square loop is not noticeably worse in performance than a circular loop and may be easier to construct.

Download program MAGLOOP4 from my website. It may provide food for thought.

Reg, G4FGQ.

Error correction :

They need be rotateable only through about 90 (ninety) degrees.

This is to ensure an antenna can always be directed towards maximum signal even when there are 3 or 4 plastic guy ropes from the top of the loop which can prevent a complete rotation.

As far as an "optimum" height, it seems that a loop oriented such that it lies in a vertical plane, such as the one you have and Reg is describing is not going to perform better as you change the height, once you're far up enough to eliminate ground return losses. In fact, my little toy EZNEC model at 14Mhz with a 4' loop shows the development of high angle lobes if you increase the height of a vertical-plane magloop.

Seems though that if you oriented the loop such that it was in a horizontal plane and put it at a good "DX height", up where a dipole would start to give good low angle radiation, you would get an omnidirectional azimuth pattern but the elevation pattern more like a dipole at that height. This could be advantageous if you have a high support.

So if you're down at 3.5MHz or something, loop in the vertical plane near the ground is the way to go, as you'd not likely be able to get the loop up high in terms of wavelengths.

Seems, though, if you had a 20m (1 wavelength @ 14MHz) high tower with low windload capability and wanted to put up a horizontal-plane loop for 14MHz, you'd get more gain at low angles than a near-ground-mounted vertical-plane loop.

It's analogous to the situation with a ground mounted vertical vs. a high dipole. The ground mounted vertical has better low angle radiation than a low dipole, but not better than that of a high dipole, and leads to the usual situation of verticals for the low bands and horizontal antennas for the high bands.

> of the loop?
>
==========
In principle, it doesn't matter.

But it is important the capacitor is located diametrically opposite to whatever arrangements there are to feed the loop.

Ideally the loop should, as far as possible, be isolated and be allowed to find its own electric balance with respect to ground.

The capacitor itself is likely to be unbalanced with respect to ground. So it it is better to place it as far as possible from the ground and everthing else, i.e., at the top. The highest voltages are concentrated at the ends of the loop connected to the capacitor.

It is best NOT to connect the main loop to the feedline. Use a small coupling loop in the same plane as the main loop and about 1/5 of the diameter if the coax is 50-ohms. For 75-ohm coax it is about 1/4 of the diameter.

Isolating the main loop from the coupling loop and feedline prevents RF current from finding its way on to the feedline.

If the capacitor motor is not very well isolated from the capacitor itself then place an RF choke in the bunch of control wires near to the motor. Bring the control wires down from the motor across the loop diameter and in a neutral electric field. Anything which comes down vertically across the diameter is in a neutral field. It could be a metal mast to support the motor and, via the motor, the top of the loop itself.

In general, having the capacitor at the bottom of the main loop is more likely to unbalnce the capacitance of the loop to ground.

Reg, G4FGQ.

Tie a knot in the coax, and pull tight until the loop inductance
resonates with the capacitance.

Always wondered if that one would work...

The first thing to do is define precisely what you want the choke
balun to do and why. Then you might be getting somewhere.

If you don't know, you don't need one. Then you can forget and stop worrying about it.

Some trees would help camouflage that thing. I'm all for putting up the antenna you're legally allowed to put up, but it's a shame that one has to anger the whole neighborhood because everyone basically ends up with an unobstructed view of your 4 element SteppIR even when the tower is retracted to 21 feet!

It's too bad you can't buy and transplant 30 foot trees!

That video makes me want even more to live in the country when I'm done in grad school. Fortunately, neither my YL nor I would want to live in a neighborhood where all the houses look exactly the same and there are no trees...

I wonder if he could camouflage that as a giant, whole backyard patio umbrella. 'Course that's probably not legal.

A choke balun made from RG-58 coax cable, centred on 145 MHz and
having a high impedance over the 2 meter band has the following
dimensions -

6 turns of RG-58
Length = 30 mm = 1.2"
Diameter = 37.5 mm = 1.5"

Measurements are between centers of turns.

Make it neatly.

Reg, G4FGQ

43 material ferrite beads are quite effective at VHF. I would (and do)
take this route at VHF because they're more compact than a coax choke,
and you don't need too many of them to get substantial choking
impedances.

I was pointed to this PDF (big) for impedance vs. frequency curves.

http://www.fair-rite.com/newfair/pdf/15th_Edition_Fair-Rite_Catalog.pdf#page=1

A 2643012702 bead of the sort that fits (most of the time!) over RG-58
has a typical 1 turn impedance of 38 ohms at 100MHz according to the
catalog. You can decide on an appropriate choking impedance and stack
beads in the number you need.

Don't worry about chokes further down the coax unless you're really
having feedline radiation problems. A choke at the feedpoint will take
care of RF current conducted onto the feedline. If you're getting
induced currents on the feedline, get it away from the antenna! It's
VHF! :-)

I'm using bead baluns on my 6m moxon, my 2m and 432m yagis... I might
not notice the difference without them, but I had a box of, I dunno,
800 of those 43 material beads lying around, so I'm using bead baluns
for everything.

I've hung around r.r.a.a. and read many posts about cracking at high
power if the choking impedance is low enough that more than a few watts
are being dissapated in the choke.

I've also read quite a bit about conducted RF from all the junk
electronics in everyone's house being kept OFF THE ANTENNA by an
effective common mode choke, and this is why I'm going to keep using
them whether I feel that I need a balun or not for antenna pattern.

Back when my very understanding parents let me bury all my feedlines
for 40 feet under the lawn to build my high-school antenna farm, I
didn't worry about choking off shield currents, but now that I'm in an
apartment, everything I can do to keep antenna and noise separated is
going to get done.

I didn't answer because he: 1. chose to change the subject and
2. refused to answer my question. So he didn't deserve an answer.

I wouldn't appreciate my EE degree any more if it had been harder
to obtain. I just might not have obtained it. But that is an
irrelevant diversion thus no answer from me.

If the goal is "better" amateur radio operators, let's make
obtaining a license so difficult that only two people can
obtain it.

First, at 100 watts do you have a license?

I'll keep that in mind while I'm enjoying a CW contest at 40 plus a minute.

Actually, considering the costs, I'm thinking perhaps just 1/2 inch pipe.
I did some modelling and the difference between 1/2 inch and 2 inch pipe
is really only 6db and I can get nice flexible 1/2 inch pipe.

> For multi-band operation you will be best with a motor-driven vaccuum

> and 40m bands can be covered. It depends on the minimum capacitor
> setting and loop perimeter.

I'm thinking more on the lines of switching capacitors in and out. I
also don't care if the feedpoint SWR goes up fairly high, as long as my
tuner can flatten it. I can make some pretty good fixed capacitors from
heliax.

Rotation is probably not an option here as it has to sit on an apartment balcony. There will be some ground clutter, too, from the balcony railing. But that may not be as debilitating as it looks because the whole business is 10m up and any currents in the aluminum balcony railing tend to add to the radiation, though the pattern can become moot.

> whatever arrangements there are to feed the loop.

I have not found this to matter. And I think MFJ's commercial loop tuners all work at the feedpoint. The trick is in getting a good coupling to the loop. If you do that, the placement of the capacitor is probably irrelevant, since the loop is, after all, just a circle with current in it.

> Ideally the loop should, as far as possible, be isolated and be
> allowed to find its own electric balance with respect to ground.

Yep.

> the diameter.

I'm using a different arrangement here. I'm connecting the center conductor of the feedline to one side of the loop and using a small capacitor (gimmick actually) to couple the coax shield to the other side, with the capacitor (essentially it's the inner conductor against the shield) being across the break at the feedpoint. Darn thing works, though.

> Isolating the main loop from the coupling loop and feedline prevents
> RF current from finding its way on to the feedline.

Then again, this may be a feature, not a bug!

From: "J. Mc Laughlin" <jcm@power-net.net>
Message-ID: <126af3kibhk17eb@corp.supernews.com>
Source record: 59675

Dear MRW:

The university where I teach licensed a 100 watt FM station last year. The transmitter was placed near the base of the tower that supported the transmitter's antenna.

The studio was some 1000 feet away from the transmitter. A cable containing multiple shielded pairs was run from the transmitter to the studio. Every low power FM broadcast transmitter that I looked at had provisions to make easy remote control.

My suggestion is to mount the transmitter near the antenna and run control cables down to the studio. A short run of coax is likely to have acceptably low loss.

Good luck. 73 Mac

Hi Dave,

Only 6dB, hmmm? Considering the following:

>I'm thinking more on the lines of switching capacitors in and out.

the switch contact resistance will probably swamp out any perceived
efficiency gain achieved by added pipe diameter. You may be lucky and
have them fuse themselves closed - luck could run the other way and
they fuse open.

Even if they don't fuse (gee Richard, its only ~100A RMS loop current
at 10W EIRP (assuming Rr of about 0.001 ohms)... but it will be hard
to achieve such high EIRP), it is some more loss resistance to drive
efficiency even lower.

I wondered about the effectiveness of the switching arrangement given
the very narrow bandwidth of the antenna, it might take a hundred
discrete tuning combinations to effectively cover the 80m / 75m band.

There's a good fight brewing in QEX magazine land. Eric, K8LV, wrote a pretty good article on directional wattmeters. But he spent a lot of space asserting that the notion of forward and reflected power in a transmission line is merely for intuitive convenience, isn't real, and should be abandoned in favor of unidirectional power flow and lumped analysis at a single point.

Whoo Hoo. The letters will be fun. Especially if Eric attempts to extend his assertion to a case not-as-special, such as not-steady-state or a point in 3D space.

Too bad it wasn't here. Bet we'd get a couple dozen posts before the weekend's out. Anyone want to take Eric's side?

K8LV is like the person who is satisfied with the Sun God riding
his chariot across the sky every day as a model of reality. He seems
to believe in a Standing Wave God who wills standing waves into
existence without the necessity for a forward traveling wave and
a rearward traveling wave to exist. It reminds me of what Einstein
said about models of reality needing to be simple, but not too simple.

Over the years, I have challenged anyone on this newsgroup to create
a standing wave in a single source system without having the existence
of a forward wave and a reflected wave. Nobody has furnished any proof
that standing waves are possible in a single source system without the
existence of forward and reflected waves.

Reflected energy is readily apparent using a time domain reflectometer.
Reflected power is easily detected and dissipated using a signal
generator with a circulator and load. A bit of modulation proves that
the reflected wave has made a round trip to the mismatched load and
back to the circulator load.

With the following example, I have shown that, during steady-state,
there are 300 joules of energy in the transmission line that have
not yet reached the load.

100W---one second long 50 ohm lossless feedline---291.5 ohms
Pfor=200W--> <--Pref=100W

There are no impedance discontinuities between the source and the
load and EM energy travels at the speed of light. The 300 joules
cannot exist anywhere except in the forward and reflected waves.
Without the existence of forward and reflected waves, there is
nothing to support standing waves. That the energy moving in each
direction is difficult to separate is no reason to assert that it
doesn't exist. According to the IEEE definition of power, the
potential for doing work is power. The 300 joules stored in the
above transmission line have the potential for doing work after
the source is powered down. That the work actually performed is
not useful work is irrelevant.

Anyone who doubts the existence of reflected energy should do a
second by second analysis of the above example starting at power
up. The technical facts become undeniable after a few seconds.

> Whoo Hoo. The letters will be fun. Especially if Eric attempts to
> extend his assertion to a case not-as-special, such as not-steady-state
> or a point in 3D space.
>
> Too bad it wasn't here. Bet we'd get a couple dozen posts before the
> weekend's out. Anyone want to take Eric's side?

K8LV even contradicts himself in his own article. He says the Z0 of
the line "literally forces all power flow to occur in 50-ohm waves
on the line". In the above example, those 300 joules per second are
necessarily flowing in the one second long line since they cannot
stand still. Where are they if, as K8LV asserts, the Z0 of the line
is forcing a V/I ratio of 50 ohms? They can exist in only one place,
in the 200W forward wave and 100W reflected wave each of which forces
a V/I ratio of 50 ohms, just as K8LV asserts.

Exactly the same thing happens when standing EM waves of light are
formed in free space. Let's see K8LV explain that one without the
existence of forward traveling light waves and rearward traveling
light waves. How do these quotes agree with standing waves of light?

"... the forward and reverse waves do not exist separately ..."

I think I can hear a multitude of physicists laughing at the assertion
that standing waves of light do not require the separate existence of
forward and reverse waves. QEX was interested in publishing an article
of mine with light wave examples until they realized the implications
of those technical facts.

This is just one more example of the dumbing down of amateur radio
accompanying the dumbing down of the US educational system in
general. Unfortunately, it seems to be a trend that cannot be
reversed because it is the biased view being pushed by the ARRL
and its supporters.

2347. Antenna cables in metallic conduit?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-05-13 15:12:14 UTC
From: shoppa@trailing-edge.com
Message-ID: <1147533134.463541.318940@g10g2000cwb.googlegroups.com>
Source record: 59589

Is there any advantage or disadvantage to running my antenna cables (mostly RG-8 and some RG-58 and Twinax for loops) in metallic electrical conduit, probably 1/2" EMT?

The shack is in the basement and various antennas come in through the roof/attic, three stories up. Currently the antenna cables drop down a fairly clear hole shared with some vent pipes and Ethernet (CAT-5) and phone wires.

I have some 1/2" EMT with the tools and some experience bending/installing it.

I do observe some RFI between computers etc. throughout the house and the ham/SW antennas. Would putting either the coax or the CAT-5 or both (separate conduit) help any?

I'm guessing the antenna and ethernet conduits, if I do it, should be bonded to the household ground near the electrical panel etc. for safety. Am I likely to get any grief from the electrical inspectors by using metallic conduit for running non-AC cables, or for bonding it to the same grounds? To me it's a no-brainer that a common ground would increase safety but in past electrical inspections they've given me some minor grief for the antenna cables which were well-grounded near the entrance panel. They pointed to a really really crappy CATV installation and said that I had to do it that way.

Tim.

There are no RF disadvantages of running the coax in a metallic conduit.
YOu may get some shielding and also some lightning protection if the conduit
is grounded, but it is doubtful it would really be noticed if good quality
cable is used. YOu just can not run unshielded twin lead or ballanced line
in the conduit.

Cecil,

Why would anyone try to prove that the basic math of adding sinusoidal functions is incorrect? To the contrary, you are the one who insists that a standing wave and its constituent traveling wave components are somehow different and unique. No one denies the simultaneous existence of standing waves and traveling waves.

Isn't superposition wonderful!

Actually, it was you who made that assertion and thanks for the
opportunity to quote you once again:

Gene Fuller, W4SZ wrote:
> In a standing wave antenna problem, such as the one you describe,
> there is no remaining phase information. Any specific phase
> characteristics of the traveling waves died out when the startup
> transients died out.

So standing waves are "somehow different" from traveling waves
according to your own assertions. The traveling wave possesses
phase characteristics and the standing wave doesn't.

> Phase is gone. Kaput. Vanished. Cannot be recovered. Never to be
> seen again.

So it was you who asserted that standing wave current is "somehow
different" from traveling wave current and I agree with you. It's
obvious they are "somehow different" because they have different
mathematical equations. Have you changed your mind since your
above quoted posting?

> No one denies the simultaneous existence
> of standing waves and traveling waves.

Of course they do, Gene, that is the whole point. Here is a quote
from K8LV's article:

"I wish to emphasize the fact that the forward and reverse
waves really do not exist separately ..."

That certainly *denies* the separate existence of the underlying
traveling waves so your above assertion is false. I believe that
W7EL also denies the separate existence of forward and reverse
waves and introduced the technical term, "sloshing", to explain
what happens to the energy in a transmission line with reflections.

Funny thing is that I'm down with the slow-wave loading coil thing.
Maxwell's equations are your friend... not a very nice friend when
Bessel functions are involved, but...

Faster than light, though? Maybe the phase velocity in some tricky
cryogenic world, but I dunno...

Haven't seen much on superconducting antennas here... I read a paper
once with a superconducting magloop but they forgot to make the
matching network superconducting too.

Let's get the "bizarre but REAL" antenna thread going.

Wouldn't you like to have a QRP CW rig with a 3" magloop for 20m on the
top? The thermos full of liquid nitrogen is kind of a pain to lug
around...

Anyone built a "genetically" designed ham antenna yet? Might be a good
way to go for the "I have 50 feet between two trees to put up an 80m
dipole" crowd.

Maybe we could develop a combined performance+aesthetics genetic
algorithm to design efficient shortened vertical dipoles that look like
nice pieces of modern art and have a nice low voltage section to run
the coax out... you run the electromagnetic algorithm, weed out the
weak designs, then you have your neighbor click the most attractive
five and throw the rest out, and repeat!

I don't think anyone is trying to be "deliberately being dumb", more like
"naturally being dumb" and not knowing it. :-)
Reality is that quality of technical material in ham publications is
slipping, heading for stuck on stupid. Add cheapening of ham ticket exams,
push for mass and no exam recruiting of new hams (a la CB wizards) in effort
to boost numbers and few bad apples with it - you get the picture of
deteriorating standards.

When W8JI had a presentation at Dayton's Antenna Forum and spoke about his
"famous - same current along the antenna loading coil", I came to K3LR
(forum leader) and N6BV (ARRL Antenna Book editor) and pointed out that
perhaps there is an error in W8JI assertions, I got this in private mail
from the "guru":

"When you pull people aside at Dayton to bitch about me or others or make
wild crazy statements it just makes you look worse and worse to the people
you are trying most to impress. At Dayton two years ago several people came
up and told me your tried to start conversations about me with them, or that
you started bitching about me."

Sooo, looks like one has to take some articles in ARRL publications with
biiiig grain of salt. Goofy stuff gets through, real expert material gets
swept under by "know-it-alls" in charge, Goofy is right and Right is not
important anymore. "Gurus" beat their drums into the publications and great
confusion ensues.

As far as SWR, I always tried to avoid it by matching, designing antennas to
have impedance of the feedline, and the TX/Amp output matching the feedline

impedance. Standing Wave Ratio always implied two waves - forward and reflected and their superposition. Why waste power in "confused" standing waves, when I can make sure that the waves are marching forward towards the antenna and be radiated. Let the waves stand in the antenna, where they belong, doing radiating and not in the lossy feedline.
High SWR is not imaginary, it is real, can create excessive voltages, dielectric losses and melt the coax.

Happy Mother's Day to all the mothers that did not abort us!
God Bless them and thank you!

Yuri, da BUm

I can't understand the aversion to simple, 2-wire, choke baluns
instead of complicated (can be lossy), awkward to adjust, narrow-band,
balanced-to-unbalanced tuners.

Praps it's because it is how a broad-band choke balun works is not
understood. Yet it is childishly simple.

Some people are happy only when tormenting themselves in their hobby
of amateur radio. I suppose the more difficult it is to tune up the
greater the satisfaction to be obtained in accomplishment.

There's no accounting for human idiosyncracies. Everybody please carry
on enjoying yourselves as normal.

Reg.

Let me just relate my personal experience. I submitted an article
to QEX which mentioned light wave theory as explained in "Optics",
by Hecht. An (un-named) QEX employee, with whom I was dealing, had
"Optics" as a college textbook and was very interested in the subject.
He suggested that I expand the light wave theory section of my article,
which I did. After about four revisions, he suddenly stopped responding
to my emails. A couple of months later, I received a rejection letter.
That was well over a year ago.

Two QEX articles have recently appeared covering exactly the same
material as my article but with different slants. QEX still will
not answer my emails and will not publish my letters to the editor.
My treatment by QEX is more akin to religious shunning than
anything else.

I am convinced that the QEX employee that I was dealing with is
deliberately publishing dumbed-down material because he previously
indicated that he knows different from his college optics course.
He is most probably being directed to do so by his superiors because
he was, at first, enthusiastic about publishing my article which
is available from my web page below.

Hi "Buck"

The RoomCap Antenna is NOT an EH-Antenna.
You should know that, if you have read the homepage of
the antenna.
If you really want to know how it works, and you want be be the owner
of such antenna, you may obtain the construction guide.
You find all this information on:
http://home.tiscali.ch/hb9abx/ant--abx-e.htm

Please take the time to read all, then you get the right information

with best 73

Felix HB9ABX (the developer of the RoomCap Antenna)

BTW: I sent you a normal email after your first request.

Dave wrote:
> tell us more, 'dual-z0 shortened stub' sounds like something interesting.

In my quest to explain the phase shift in a 75m bugcatcher
coil, I thought about a dual-Z0 stub. The shortest 450/50 one
I have come up with that causes the maximum phase shift is:

---19 deg of 450 ohm line---+---18 deg of 50 ohm line---open

Believe it or not, that is an electrical 1/4WL stub with a
whopping 53 degrees of *lossless* phase shift occurring at the
'+' impedance discontinuity point. Are there any applications
for a stub that is physically 0.1 WL long instead of 0.25WL?

It could be shortened even more by using 600 ohm line with
50 ohm line. On top of everything else, the current in the
50 ohm section seems to be much lower than the current in
the 600 ohm section thus reducing the losses in the stub.

From these experiments, I have concluded that the phase shift
in a 75m mobile loading coil may be in the ballpark of 20 degrees
while the phase shift in the stinger is in the ballpark of 20
degrees with the majority of phase shift coming from the
impedance discontinuity between the loading coil and the stinger.
So neither side of the years-long argument was right or wrong.

Just a question about coax cables:

I know that a coax cable does not radiate (if common mode currents properly suppressed) because both conductors are apparently "in the same place" (wouldn't know how to express it in more technical terms).

Now the question is: This is true for big distances from the coax, but is it also true when you get very close to the coax? Imagine a conductor taped to the outside of a coax for some meters. The capacitive coupling to the braid is much higher than the coupling to the inner conductor. Would it pick some of the current in the coax. If not, why not?

(apart from fun I'm really interested in the answer as I'm not quite sure if a coax running parallel to unshielded and not twisted computer cables would pick harmonics from it on RX or create interferences on TX)

Wow Allison, 3" or 4" conduit is pretty heavy duty stuff, although I do appreciate the thought of "run the conduit once and then just snake more cables through as you need them".

I was thinking of 1/2" EMT and running individual conduits for ethernet/CAT5 and each antenna, with the end of each conduit coming out in an appropriate part of the shack.

Another reason for doing multiple smaller runs of the EMT is that there is 2nd-story room where the cables run through tacked onto the wall, it'd be nicer to have whatever conduit goes through that room to be as unobtrusive as possible. I was thinking of multiple 1/2" EMT's up against the wall, although maybe a single fat conduit might be less obtrusive.

3" EMT seems to be about ten times more expensive than 1/2" EMT. Although it undoubtedly could carry more than ten times as much RG-8 :-).

Tim.

Instead of EMT you may want to use some of the plastic electrical conduit.
Not sure if it would meet the building codes for what you want by going from
one floor to the next. It is sort of a grey colored PVC type of pipe.
Probalby not really PVC but another plastic.
It will do nothing for the shielding, just may be neater to run than the
plain coax.

no... and yes.... there would be some pickup, but only from leakage through an imperfect braid. because the current is on the inside of the shield it would not couple to the cable on the outside. the electric and magnetic fields are contained completely inside the shield.

Here's why it doesn't radiate: In a coaxial cable with a solid shield, the differential mode current is entirely inside the shield. Current and fields penetrate only a very small distance from the inner surface of the shield, and no significant amount ever makes it through to the outside. This is assuming that the shield is at least several skin depths thick, which is a good assumption at HF and above.

Common mode current, by contrast, flows on the outside of the shield, and its field radiates outward from there.

> Now the question is: This is true for big distances from the coax, but
> is it also true when you get very close to the coax? Imagine a conductor
> taped to the outside of a coax for some meters. The capacitive coupling
> to the braid is much higher than the coupling to the inner conductor.
> Would it pick some of the current in the coax. If not, why not?

Again assuming a solid shield -- the center conductor carries a current and therefore creates a field. The inner surface of the shield carries an equal and opposite current and also creates a field. But those fields are equal and opposite, and cancel at all points beyond a thin layer on the inner surface of the shield. Since there's no significant field at any point outside the shield, it doesn't matter where you look, you won't find any, and there isn't any field to couple to anything else.

In reality, any shield other than a completely solid one (such as the shield of hard line or semi-rigid coax) will leak some because of gaps or holes. And the field will couple more strongly to wires which are close than those which are far away. Whether the amount of leakage is significant or not depends on the application.

> (apart from fun I'm really interested in the answer as I'm not quite
> sure if a coax running parallel to unshielded and not twisted computer
> cables would pick harmonics from it on RX or create interferences on TX)

You might get enough leakage through the shield of ordinary coax to cause problems in both cases. It depends on the transmit power level, the signals in the wires, the length over which they're bundled, the frequencies involved, the quality of the shield, and so forth.

Separating them even a small distance would reduce the coupling considerably. But you're likely to have more trouble with common mode current.

Cecil,

You keep making the same mistake. Yes, you can analyze traveling waves instead of standing waves if you so choose. However, there is not one bit of additional physical information in the traveling waves that is not in the standing wave. Any "phase characteristic" is simply a function of the mathematical manipulations you use.

Perhaps someday you will actually understand superposition, but I won't hold my breath.

Howdy antenna aficionados!

Wanna FIGHT?

Here is another misconception propagated by "guru" W8JI, like "there is no electrostatic shielding, the grounded piece of tubing (shield) IS the antenna."

Let the games begin! (I will hold my horses for a while :-)

As posted on TopBand@contesting.com reflector:

>>>
Subject:
"The June, 2006 QST has an article about a 160m RX loop.
Comments, advice welcome."
73,
Tim K3HX

Tim, et al,
I just received the rag here. Very interesting this article, in light of the many discussions on this reflector and antennas reflector, concluding by our best experts that a shield contributes to NO USEFUL function whatsoever in such a receiving loop! It just essentially becomes electrically the loop itself; the shield's outer skin IS the antenna. No S/N ratio advantage, no anything except adding to a very critical balancing result. No noise discrimination, no magic. So what gives with this mythological article?
73, Roy K6XK

W8JI wrote:

Roy and all,

It appears QST isn't as careful as they used to be years ago.

It is a very well known physical property of a "shield" more than several skin depths thick that essentially nothing goes through that shield. It's a Faraday cage, and when the time-varying electric field goes to zero so does the magnetic field. This is explained in nearly every handbook (even ARRL publications) and is the reason coaxial cables have that "third path" on the outside of the shield for common mode currents. This is why a bead balun or a coil of coax works to stop common mode on the outside of the shield and does not affect the stuff inside the cable.

Obviously any technical explanation that requires fields to go through the shield isn't accurate.

It is also a very well known fact that radio waves are electromagnetic, and the interference (unless in the induction field area of less than a half wave or so) is a radio wave, and like all radio waves it is neither magnetic or electric. It has a fixed ratio or electric to magnetic fields. It is also established that a very short distance from a small loop the predominant field is electric, not magnetic. Clearly a shield can't "filter" noise, since noise is not field sensitive.

So what does the shield in a loop do? The shield is actually the antenna element. The shield is actually what receives (and/or transmits) the EM wave. NOT the wire inside the shield. The wire inside the shield simply couples whatever device is connected to the antenna (the loop's shield) to the receiver.

If we have a poor coupling system to the loop, how we configure the shield can certainly affect the balance of the loop and the common mode current. Say we use an unbalanced line or we use an unbalanced amplifier directly attached to a loop. Now we have created a problem, the feedline feeding the loop acts just like part of the antenna system. We have an unbalanced feedline or amplifier tied to a balanced antenna, and so every conductor going to that point acts like part of the antenna system. We can couple noise and signals picked up by the feedline shield and everything in the house to the input of the receiver.

I go through this problem in detail at:

http://www.w8ji.com/magnetic_receiving_loops.htm

If you read carefully you'll see no has ever said the shield and how the shield is connected won't change the system when the system is not designed correctly. When the feedpoint is done correctly, the presence or absence of a shield has no effect at all on the system. All the stuff about the shield "filtering" the fields and blocking the electric field is nonsense. But some construction methods do result in better loop balance.

The characteristics of an improperly done feed system are affected by the construction of the loop, but that isn't because the shield is necessary or that a solid shield behaves differently than braided shield. It's because something was more wrong with the construction in one system compared to the other, not because of the shield quality.

Greetings,
I have come by a Singer Stoddart 94592-1 rod antenna coupler. It is a cube about 4.5" is green and has a telescoping antenna on top affixed by a screw on BNC type connector. The output is BNC and there are two binding posts for B+ input I believe. I haven't been able to find a thing on the www about this device, although, i did see one listed on ebay once for big bucks. Does anyone have any info on this device they would share with me?
The device is for H.F.
Dave - KA9SRU

Gene Fuller wrote:
> However, there is not one
> bit of additional physical information in the traveling waves that is
> not in the standing wave.

I agree with you but W8JI and W7EL have rejected the concept that
there is any phase information in the standing wave current magnitude.
They have rejected any use of the arc-cosine function in calculating
that phase. The following graphs show the difference in the standing
wave current and the traveling wave current.

http://www.qsl.net/w5dxp/travstnd.GIF

The standing wave current phase contains zero phase information
as you have stated. As you say, all the standing wave current
phase information is contained in the magnitude but the arc-cosine
function for obtaining that phase information has been rejected by
the experts. For the traveling wave, there is phase information
contained in the phase, none in the magnitude.

Every time you make a technical assertion, you support my argument.
Seems your argument is really with the side that rejects the arc-
cosine function for obtaining phase information.

Hi Sal,

I appreciate your suggestion. I am looking for radio interference more than anything. It would just be enough to note that there was interference, and its local level, on certain frequencies. It would be good to have a good clean signal per receiver to establish a base line. Some of the 'wx' only affects certain operating frequencies which makes it easy to find. You can see some of the more exotic stuff at www.sec.noaa.gov which is "right down the street." The only difference I'm coordinating it with crime and health information instead of terrestial communications. "Right up the street" another amateur discovered that lightning goes upward, in a relative handful of configurations. My experiment is not so real time. I do appreciate your idea however and plan a grounded wall box with a few of those sort amps inside. Thanks Sal. Stay dry!

>BTW: I sent you a normal email after your first request.

Someone else sent a link to an EH antenna as the answer. I guess they were wrong. Right now I cannot link to your site. For some reason, I am unable to send email to your address, I think it has something to do with spam filters. I get this periodically as someone on bellsouth sends a message to a spam trap and the entire ISP is blocked. Likewise, I have not received an email from you, probably because the address in this is fake due to the magnitude of spam generated. Someone else did forward an email from you that you send out showing that what you are doing is selling the information.

No one in his right mind would order an item in which they must agree to abide by the terms and conditions that they can't read before buying the product.

Nothing personal, but your website is anything but professional looking. I do recall the following: you rant and rave about what others have said that disagree with you or your findings about your antenna. Most, if not all these arguments, I can only find on your own site, so your defense against these allegations and the attitude you portray only distract focus from one's interest, your antenna, and instead lays it onto your frustration and other's arguments.

Additionally, you could just as easily have posted the required information about the costs and the obligatory terms and conditions of purchase of your CD-ROM.

I must say, that based on the information on your site, there is a lot of controversy over what your antenna actually is, or how it performs.

I notice that you don't actually sell the antenna, only the design information on a CD-ROM. Of course, that could reinforce the idea that you could be treading on the EH antenna design patents as someone else suggested (that your antenna is actually an EH design.)

Personally, I think you could greatly benefit by removing all the controversy, give a little more detail about your antenna and specifically, adding the details of your private email that has to be requested to learn more about the antenna.

How much are the parts required to make the antenna? After you so carefully protected me from receiving the minimum information on obtaining more information about the antenna, how do I know you aren't hiding something else such as a part you manufacture that I have to buy from you before being able to successfully build that antenna.

In all reality, you have frightened me from buying the information from you about this antenna. I would like to hear from someone who has actually gotten your disc and possibly built the antenna so I can know how it performs from someone else's point of view.

If it performs as well as you claim it does, or if it is similar to the performance of an EH per size,(for example, hypothetically speaking, a 3 foot antenna performs as well as a 1/2 wave vertical 20 meter antenna), and if the cost and skill level required for building the antenna is suitable to me, I might be interested in purchasing the plans for your antenna.

However, your website leaves me with the impression that you are afraid of being criticized, almost to the point of paranoia, and from a business standpoint, I may be the only person who does this, but I actually READ contracts before I sign them. If I can't read it, it won't get signed.

This is nothing personal as neither of us knows each other. I am not accusing you of anything, good nor bad. I am just stating things as I see them. From what I see on your website only makes me want to know more from what others who have interacted with your antenna have to say before I proceed further in entering a contract with you.

Thanks for trying to send me the email. I do get frustrated at this mess with spam filters blocking all my ham buddies and passing spam all day long.

Hi Buck and others:

EH-Antenna an RoomCap antenna:

These are two different types of antennas, as the basic principle of
the
EH-Antenna is the use of a phase shift network that shall produce a 90
degree phase shift between the current and voltage to the antenna.
This phase shift does not exist in the RoomCap antenna.
But there are further main constructional differences, which can be

seen
in detail in the construction guide.

The RoomCap antenna is working basically with the electric field which
is produced into the open space between the radiator and the counter
plane.
To achive this, a so called VARYLINK is used to feed the antenna with
an SWR of 1:1 on each band.

The VARYLINK does not exist in the EH-Antenna.

Regarding my personal email:

- First email: hb9abx at tiscali.ch

- Second email: hb9abx-1 at hispeed.ch

Note:
The first construction guides have been mailed 2 weeks ago
and arrived a few says ago. Now many HAMs are working on their
construction. Let's see their results.

When you say "Current and fields penetrate only a very small distance...", I agree for the current part, but I'm not so sure for the fields part:

As I understand it you can not "stop a field" in no way, though you can certainly nullify it with an identical but opposite field.

Then the question is whether the two fields (the one from the current flowing in the shield + the one from the current flowing in the inner conductor) nullify at all points in the immediate vicinity of the shield. I certainly believe it but would like to understand why this is so.

I guess the mathematical proof would involve assuming the braid is an infinite number of conductors equally spaced around the center conductor, each having it's infinitesimal share of the shield current, and integrating all of their fields at the point of interest (Would probably be able to do so back when I was at university but now it is too strong math for me). Would this be a good approximation of the problem?

Thanks four your answers.

I was forgetting you normally use coax in a unbalanced configuration
where the braid is supposed to be at 0 voltage so only currents matter.

Would all this still hold if you used the coax as a _balanced_
transmission line? (unusual but -I think- possible). In this case
wouldn't voltages develop on the braid that could capacitively couple to
other conductors?

(assuming perfect solid shield, ...)

the voltage on the braid is not zero on the inside, it varies along with the wave traveling along the inside of the coax. and the currents are exactly balanced inside the coax also, they have to be or it wouldn't work. this notion of balanced vs un-balanced transmission lines is totally confusing to most people, in a proper system, say just with a dummy load on a coax the currents on the shield exactly balance the current on center conductor. so why do we go through all this stuff with bal-uns?? and coax chokes?? the currents are already balanced, so WHY?? come on you gurus out there, explain this one!

An EM specialist may shed more light on this subject.

Twenty years ago, when I managed an EM lab among other responsibilities, Singer Stoddart was the #1 supplier of laboratory quality EM measuring devices. They designed and sold EM test instruments including receivers, antennas, couplers, that were traceable to NBS primary standards.

I suspect you have a very expensive coupler for a receiving dipole for measuring radiated EM noise fields.

[For about $40,000 you may find a Singer Stoddart receiver and antenna set to use with it <g>].

Any professional EMers out there??

Cecil,

You still don't get it.

When I said the phase information was gone, I meant it. Any phase information you think you find by looking at the constituent traveling waves is merely an artifact of the math. It has no physical meaning or reality. If there is anything interesting left in the traveling wave analysis, then the standing wave is not the complete representation of the electromagnetic phenomena. This is a different problem.

Yes, you can apply modulation, insert directional couplers, look at startup transients, or perform other tricks to get "real" phase information. However, that again becomes a different problem, not the original simple steady-state combination of traveling waves into a standing wave.

You bet you can stop a field. It can be stopped either by reflection, absorption, or a combination of the two. Inside an anechoic chamber, absorbing materials stop internal fields to prevent reflections. A screen room or metallic shield reflects external fields.

> Then the question is whether the two fields (the one from the current
> flowing in the shield + the one from the current flowing in the inner
> conductor) nullify at all points in the immediate vicinity of the
> shield. I certainly believe it but would like to understand why this is so.

Indeed they do. Look up Ampere's Law. If you draw a boundary through the middle of the shield or outside the shield, you'll find that the sum of currents within that boundary is zero. According to the law, that means that no net field penetrates the boundary. Because of the physical symmetry, no net field means no field at all.

> I guess the mathematical proof would involve assuming the braid is an

No, it's not that complicated, but a path or surface integration is required to use Ampere's law.

How do you define "0 voltage"? Do a groups.google.com search of this newsgroup and you'll find quite a bit of discussion about the futility of trying to define a voltage between two distant points in the presence of a field.

A coax line is balanced when the common mode current is zero. It's unbalanced when common mode current exists. See http://eznec.com/Amateur/Articles/Baluns.pdf for more information.

Voltages don't couple, fields do.

There was also some discussion not too long ago on this group about the role of current in generating both electric and magnetic fields.

The currents on the inside are always balanced -- they're purely differential mode. The purpose of baluns or common mode chokes is to reduce the common mode current which, on coax, flows entirely on the outside.

If you're driving a dummy load from your transmitter, the common mode current will be zero in an ideal system and negligible in a real system. A balun or common mode choke will do nothing in that situation.

See http://eznec.com/Amateur/Articles/Baluns.pdf for a more complete explanation.

So you alluded to phase information in the standing wave
current amplitude.

> When I said the phase information was gone, I meant it.

But you also said:

Gene Fuller wrote:
> However, there is not one bit of additional physical information
> in the traveling waves that is not in the standing wave.

We know that there is phase information in the traveling waves.
So for your statement to be true, there has to be phase information
in the standing wave.

Both of your statements cannot be true. Which one are you
willing to stick with and which one are you going to retract?

If you look at: http://www.qsl.net/w5dxp/travstnd.GIF
you will see that the standing wave amplitude is indeed
a cosine function of the phase. Taking the arc-cosine
of the normalized amplitude yields the phase angle.

I'm sorry, but you have contradicted yourself a couple of times
so I don't know which assertion you want to go with.

>>. . .

Egad. Of course I reject the notion that there's "phase information in the standing wave current magnitude". Magnitude and phase are orthogonal. There's no phase in the magnitude and no magnitude in the phase. There's no real portion of the imaginary part and no imaginary portion of the real part. I haven't a clue what you mean by "use of the arc-cosine,function to calculate that phase", but I certainly reject any method that assigns a phase value to a magnitude or vice versa. I get the total voltage or current simply by adding the traveling waves. No trig functions necessary, just simple vector addition.

Traveling waves have phase information. In a steady state system they can be expressed as phasors, which consist of a magnitude, a time phase reference value, and an implicit time varying time rotation. When you add them to get the total (which Cecil likes to characterize as a standing wave as though it's something different than just the total voltage or current), you get the simple vector sum of the constituent traveling waves. This sum is also a phasor, with magnitude, time phase reference value, and the same implicit time varying phase rotation.

In summary, both traveling waves and the total voltage or current are phasors, and both have phase.

What's so complicated about adding a couple of phasors? Cecil, you need to go back and read, and understand, your freshman circuit analysis text.

What a bunch of irrational smoke and mirrors.

I don't care less what Cecil will make of this. But Gene, do you really disagree with what I've just said?

Sonny, the feedline cannot and does not have any influence on the
resonance of an antenna. Resonance is determined by the physical
dimensions of the antenna itself.

Tell us about the antenna. How did you determine a 100 ohm input impedance?

72 ohm twin lead is available at selected suppliers. But, I am not aware
of anyone making 100 ohm twin lead. that's why I asked about the 100 ohm
value.

Source record: 59554

Roy Lewallen wrote:
> Egad. Of course I reject the notion that there's "phase information in
> the standing wave current magnitude".

And, of course, you are showing your ignorance. Let's say that
at the current maximum point, the forward current is 0.5 at 0 deg
and the reflected current is 0.5 at 0 deg. The standing wave
current at the current maximum point is 1.0 at 0 deg just like
a cosine function is 1.0 at 0 deg.

Now let's go 45 degrees away from that current maximum point. The
forward current is 0.5 at -45 deg and the reflected current is
0.5 at +45 deg so the standing wave current is 0.707 at 0 deg.

The magnitude of the standing wave current is 0.707. The arc-
cosine of 0.707 is 45 degrees. Do you really and truly believe
that is just a coincidence? Exactly as Gene Fuller said previously,
there is phase information in the standing wave current magnitude.

Here's a quote from Gene:

> Gene Fuller wrote:
>> The only "phase" remaining is the cos (kz) term, which is really
>> an amplitude description, not a phase.

Your statement above is in direct contradiction to Gene's statement.

> What's so complicated about adding a couple of phasors?

I suspect you know how to add phasors. I suspect you don't have
a clue what that answer means in reality. Please try to convince
us that the 0.707 result above for a 45 degree shift is sheer
coincidence.

Use side-by-side runs of 50 ohm coax to achieve a balanced Z0
of 100 ohms. Tie the braids together at both ends.

Feedline length has every influence on the resonance of
an antenna system if the SWR is not 1:1.

Why is a G5RV resonant on 3.7 MHz when a 102 foot dipole
is resonant on 4.6 MHz?

Truth is that the feedline can be used to resonate the
antenna system. I resonate my 130 ft. dipole on any HF
band by varying the length of the feedline. Check it out
at: http://www.qsl.net/w5dxp/notuner.htm

Roy,

I do not disagree with anything you have said. Cecil is up to his standard trick of selective quoting along with a subtle change of topic to make it appear that there are conflicts when there are none.

I am sure Cecil will find some other quote to remove from context in order to prove me wrong.

Cecil,

I have not contradicted myself, and I have nothing to retract. Only in
your imagination is there any useful phase information in the traveling

waves that make up a standing wave. There can be other waves that don't exactly balance out into a standing wave, but that is another topic.

I am not sure to whom the "we" refers in your statement, "We know that there is phase information in the traveling waves." Perhaps that is the Royal We, because it certainly does not include me. The phase information you might find is of no use, and it is simply an artifact of the mathematical analysis.

If the standing wave adequately and completely describes the electromagnetic situation, then there is no additional available from an arbitrary decomposition in traveling waves. If you try to look at the traveling waves one at a time, then you are no longer considering a standing wave.

You must mean, "If it performs as well as the EH antenna claims to perform." If it can do that, it's miraculous indeed. It's no trick to make an antenna perform as well as an EH -- a 3 foot high (fat) vertical performs as well as a 3 foot high EH.

To answer your specific question, ZIP cord is close to 100 ohms Zo.
However, it is relatively lossy (~3.5dB/100' at 10MHz).

K8ZOA measured ZIP cord characteristics and reported them here a year
of three back, Google for the info.

There were commercial low impedance twin lines for RF use, but they
are now obsolete (for good reason).

Sounds like he may be trying to match a Quad or a Loop. If I am not
mistaken, the usual way to do this is with a 75 ohm Q section.
Side-by-side runs of 50 ohm coax with the braid tied together will
yield 25 ohms because they are in parallel. Not 100 ohms. Or do I
need to dive back into the antenna book?

I should have provided a reference in my earlier posting. Your
above statement disagrees with Kraus. On page 464 of "Antennas
for All Applications", 3rd edition, Kraus shows the relative
current amplitude for a 1/2WL thin-wire dipole. He says on that
page that the magnitude is a sinusoidal function.

Would you care to explain how a sinusoidal magnitude function
is NOT associated with phase?

For everyone else: Roy had ploinked me so he never sees my
references. Therefore, he disagrees with Kraus over and over
and over.

C'mon Cecil, you know better!

The antenna is resonant 100% by itself.

100 feet of wire is resonant within a few KHz of 4.68 MHz. Period.
120 feet of wire is resonant at ~ 3.9 MHz. Period.
65 feet of wire is resonant at ~ 7.2 MHz. Period.
33 feet of wire is resonant at ~ 14.2 MHz. Period.

You are tuning a non resonant antenna to resonance with your stubs.

You changed the scope of the discussion with the exact wording of your
response. You used "antenna system". I used "antenna".

Why do you persist in comparing alligators and kittens?

What is a "sinusoidal magnitude function," Cecil? I don't have
Kraus, so I'll take your word for it that he wrote that the current
on a 1/2 WL thin wire dipole can be represented as a sine function.
Good. I can now throw away my EZNEC. I doubt very much if any of
the people who disagree with you really write anything that
contradicts Kraus or any of the other textbook writers. Selective
quoting is another low trick you like to play, Cecil. You must have
learned it in Bible class.

Most knowledgeable people know that the resonant frequency
of the antenna system can be changed by the length of the
transmission line series matching section. Why don't you
know that? Here is the SWR of my 130 foot dipole antenna
on 40m achieved by varying the length of the 450 ohm
transmission line.

http://www.qsl.net/w5dxp/swr13040.gif

Please look at that graph and then tell us that the feedline
cannot tune the antenna system to resonance.

Nobody said anything about tying the braid and center conductor
together. If the side by side run of 50 ohm coax is used as a
parallel feedline, the braids are tied together and the Z0
is 100 ohms when the center conductors are connected across
the load.

I don't recall ever having disagreed with anything I've read in Kraus. I do, however, frequently disagree with the misinterpretations and misquotations of Kraus and many other references which Cecil has made.

His frequent claims of "If you disagree with me, you disagree with [Kraus, Maxwell, Balanis, Hecht, Heaviside, Terman, God, whoever] are total baloney (to use a much kinder term than it deserves).

Yes, I plonked Cecil a couple of years ago. Seeing only the occasional text quoted by others of his bizarre ramblings is more than enough. Those which I do see reinforce my belief that I'm certainly not missing anything of technical or educational merit.

You'll need to jump through a few hoops on the FCC website, you will need to register with the FCC before you can renew. While you can't operate, your well within the time limits before the license becomes nonrenewable. Some of the VEC groups will do the renewal for you for a small fee if the FCC website becomes too daunting. I think w5yi charges about 15 bucks...

Pete

Your posting below disagrees with the information on page 464
of "Antennas for all Applications", 3rd edition.

> Of course I reject the notion that there's "phase information in the
> standing wave current magnitude".

The standing wave current magnitude is sinusoidal, according
to Kraus. How can you possibly have a sinusoidal wave without
an associated phase angle?

For a 1/2WL thin-wire dipole:
If the source current is 1.0 at 0 deg at t=0, the magnitude
of the standing wave current is cos(X) where X is the number
of degrees from the source. Your statement that there is no
phase information in a cosine function is absolutely false.

In fact, in the above example the arc-cosine of the standing
wave magnitude is the phase angle of the reflected current.
The negative of that angle is the phase angle of the forward
current.

All true, but there isn't much difference between a G5RV and a 102 foot
dipole fed with 450 ohm line to a good balanced tuner.

Back years ago I had a very effective vee dipole antenna for 80m that was
composed of two identical wires from the top of my third story shack
window insulated and tied off to trees and shrubbery. I fed it with
home-made 600 ohm line, about six feet long and tapped it directly off
the tank coil of my amplifier. It was LOUD all over the Pacific, South
America, audible in Africa, but for some reason, nothing from Europe!

You got it right. I take it you aren't a fan of the EH design? ;)

I would love to see the EH and the RoomCap in an antenna shootout
against the screwdriver and texas bugcatcher.

Yup. Singer made the NM-25 EMI receiver, too. I don't have any TM's around
any more, but there were about a dozen calibrated antennas that went with
those receivers. When you made a measurement, you referred to a calibration
chart for the "Antenna Factor" at that freq and you used it to convert the
received signal strength to actual field strength at that point. The NM-25

was the heaviest item I ever had to lug. Oof!

Those binding posts have me puzzled, though. I remember only coarse freq switching on our couplers -- nothing active inside that would take power input. Anything's possible.

Is this a single band or multiband antenna? If I recall correctly,
you can use a different impedance feedline if it is a multiple of a
half wave. At the half wave points, the impedance is the same as the
beginning of the feed.

Cecil or others here will correct the length error if I am incorrect.
But I learned about a year ago that the impedance can be corrected by
the multi-fraction length feedline of a different impedance.

Maybe this is the principal of Cecil's feedline matching system.

Does it have be twinlead? Certain LAN cable is made for 92 ohm Zo, which is
might close. Only downside I can imagine is the small size of the center
conductor: might limit XMIT power.

please consider writing or e-mailing a comment about how important the
real-time solar wind data is to our hobbies and emergency HF comms.

Please do not crosspost any replies

Solar Wind Comment Period Nears Its End

On April 3, 2006, the National Oceanic and Atmospheric Administration
(NOAA) issued a press release announcing a call for public comment on the
value of continuing real-time solar wind data, and products derived from
such data, provided by the Space Environment Center. Since that time,
NOAA has received many thoughtful, compelling comments regarding this
issue. It is obvious that people put their valuable time and effort into
expressing themselves, and their input is most appreciated.

There is still time to add your comments, but time is running short. As
stated in the April 3 press release, the comment period continues until
May 18. All input is important, so, if you haven't voiced your opinion
yet and would like to, please take the time to do so. Please send your
comments to:

solar.wind.comments@noaa.gov or contact:

NWS Contacts: Beth McNulty or Dorothy Haldeman

Source record: 59438

ANTENNA DESCRIPTION: I recently installed a horizontal loop antenna for 75 meters. The antenna wire is #12 multi-stranded tinned copper with 600 volt TEW insulation. The antenna is fed within one foot of the NW corner, via 25 ft. of 450 ohm twin lead to a 1:1 balun then via air dielectric RG/8 (21.1 ft.) then to a AT-1500CV. The formula 1005/f was used to figure the length and to cut the wire. However, due to the low height about ground (24-26 ft.); the ground capacitance changed the antenna resonance considerably. The target f (frequency) was 3.9 MHz with 257.7 ft. of wire. After installation in a rectangle configuration at 25+/- feet, the resonate frequency was 3.452 MHz. With a tuner matching the antenna to the "rf" generator (transceiver), the NVIS signal met the 100-200 mile range that was estimated. The antenna was tuned - cut (shortened) to increase the resonate frequency into the 75 meter phone band. After some estimating of desired length at the low elevation and cutting and pruning a resonate frequency of 3.790 MHz was obtained, that has a VSWR of 1.6 to 1. The resonance was found with an MFJ-269 without the tuner, 1.6:1 @ 3790 KHz. The tuner matches the load to 50 ohms for the PW-1. The area of the loop decreased and the perimeter length is 229.5 linear feet. Again with the use of a tuner throughout the phone band produced a NVIS signal range that was very good. K4WYS

> Any one know what power level an F connector can operate?

In real use it's probably better than a phono plug, and for example
Heath radios use phono plugs (HW-101 etc.) up to the 100W power level
up to 30MHz.

If anything the F connector is going to be a better impedance match
into the VHF than a phono plug!

Actual limit (if you want to push to the hairy edge where the connector
is getting damn hot) will depend on frequency, SWR, cabling, etc., that
you don't tell us.

Tim.

Here is the exchange on the subject from TopBand reflector:
>K3BU< (...)
and W8JI responses:

> Tom is confusing Faraday shield with Electrostatic shield
> and whole reasoning that the grounded shield of small loop
> antenna is THE antenna is all wrong. Wire loops inside the
> electrostatic shield are perfectly OK to receive the RF
> and ARE the antenna.

It's a very well known property that nothing passes through
the walls of a shield more than several skin depths thick.
This is because skin effect keeps the current in the outside
layers and the core of the shield wall is dead. This is the
very thing that allows our coaxial lines to behave like
three conductors, a center conductor, a inner wall, and an
outer conductor. The physical behavior of a shield does not
change with application.

>Electrostatic shield in small loop antennas reduces the
>interference, electrical noise locally generated (prevalent
>electrical fields).

Not so Yuri.

First an electrostatic field by definition is a non-changing
field. Static is stationary or unchanging, and things that
aren't changing can't make RF noise.

(Here he is confused about electrostatic shield, "electrostatic field" and
electrical field and just like with loading coils case, confusing the issue
with behavior of ALL shields, Faraday, Electrostatic, coax, etc. applied to

a wrong case. - Yuri)

The field from an accidental transmitter (noise source) is just like the field from any intentional signal source like a transmitter. There is absolutely nothing that says the field has a high field impedance (electric field dominant). Even if it was a high impedance at the source, just 1/10th wave or so from the source the field would change to a low impedance.

We can't filter noise by virtue of field impedance or a shield. Even if we could, the noise source in the nearfield would randomly field dominant depending on distance and source charateristics.

The only thing the shield can do at radio frequencies is change the system balance.

Not much difference in performance. Lots of difference in the
impedances seen by the tuner. For instance, built-in autotuners
will usually match a G5RV somewhere on 80m, 40m, & 20m. There
are usually certain troublesome lengths of 450 ohm line used with
a 102 foot dipole that will prohibit a match by built-in autotuners.

> "phase information in the ... magnitude".

Actually, I don't think it's "ridiculously ignorant" at
all. If all you have is the value of current at one point,
you can't possibly tell anything about the phase. You need
to compare it to something - itself even - somewhere or sometime else in
order to have an idea of phase. Here's what I mean: suppose I have a
piece of wire of unknown length, excited by an unknown frequency, and
picking a random point on the wire I measure 1.73 amps. What is the
phase? You're trying to square the circle and hear the sound of one
hand clapping at one and the same time, Cecil. Of course, in your
case, you know the length of the wire, the frequency of the wave and
its wavelength, and you think you know the current distribution
on the wire (a half wavelength dipole) so you don't need anything
but a ruler to find what you're looking for. Of course, you have to
decide what you mean by the term "phase." Try not to get a permanent
headache thinking about it.

If there is reflector (impedance bump) in their way.
If W8JI waves are not reflected or opposed, then they would propagate
merrily into the ethernity and become the law of the RF jungle and other
pagan believers would worship them and praise the radio guru.
Waves have frequencies and sines/cosines, so this is related to antennas,
unless, of course there are those who "know better" :-)
Jus' stirring the pot...

i.e. at the antenna. You're right, neglecting losses, the antenna impedance is repeated every half wavelength. Neglecting losses, that 100 ohm antenna feedpoint impedance will be repeated at half-wavelength intervals for *any* feedline Z0, including 50 ohm coax.

The principal of the feedline matching system that I use is that every SWR circle crosses the purely low resistive point at a current maximum point. For dipoles that are 1/2WL on the lowest frequency of operation, the current maximum point is the ideal point at which to feed the antenna system. Adjust the length of the feedline until the current maximum point is at the transmitter and you will usually not need a tuner at all.

> screwed up the resonance, does anone know of such an animal?

Let's take a look at how the 450 ohm feedline "messed up the match". The SWR on the 450 ohm feedline will be 450/100 = 4.5:1. A feedline length equal to a multiple of 1/4WLs will transform the 100 ohms to ~2000 ohms or a 50 ohm SWR of 40:1 which is probably out of the matching range for built-in autotuners, for instance. You can change the impedance seen at the tuner back to 100 ohms by adding or subtracting 1/4WL of 450 ohm line which will make it a multiple of 1/2WL.

As someone else said, one of the most common ways to match a 100 ohm antenna is to use 1/4WL of 75 ohm coax and then 50 ohm coax the rest of the way. Instead of "messing up the match", it fixes up the match. The SWR on 75 ohm coax would be 100/75 = 1.33:1. The impedance at the end of the 1/4WL matching section would be 75/1.33 = ~56 ohms, a good match to 50 ohm coax.

If you are wanting to use the antenna for multi-band operation, change the length of the 450 ohm line until the match is not "messed up".

2459. Re: F connectors

Newsgroup: rec.radio.amateur.antenna
Date: 2006-05-15 15:00:49 UTC
From: John Ferrell <johnferrell@sprintmail.com>
Message-ID: <l85h62pucaufi76aar1dcs8qdj840h6t5j@4ax.com>
Source record: 59451

I was being intentionally vague. I was hoping for some experiences or maybe even documentation. I have never seen it for anything other than small signal use.

The question arose while experimenting with an RV antenna on a fiberglass Winnebago. I ordered a 12 foot piece of RG59 with connectors expecting BNC's. What I received was F connectors. I am inclined to simply try them.

The initial reasoning was flawed anyway. I am planning a vertical 2 meter dipole, hence the 70 ohm cable. Since I am feeding it with a 50 ohm transceiver output there is going to be a little mismatch wherever I go. The transceiver does have a maximum output of 50 watts but the current magmount in a thin sliver of fender does not do well with that now. RF gets back into the laptop with the GPS software...

I bet that is more than any one wanted to know!

glenn.b.dixon@gmail.com wrote:
> It looks like Dave successfully excited some natural frequencies in the
> group for some weekend entertainment. Congratulations.

I don't see how there can be any argument. The standing wave
current envelope magnitude pattern pictured in Kraus is a cosine
function where the angle of the cosine function is the number of
degrees away from the feedpoint. If the feedpoint current is 1.0
amps at 0 degrees, the standing wave current magnitude in Kraus'
1/2WL thin-wire dipole has the following pattern.

degrees away
from feedpoint current magnitude
0 1.000 amps
30 0.866 amps
45 0.707 amps
60 0.500 amps
90 0.000 amps

How can anyone defend an argument asserting that standing wave
current magnitude contains no phase angle information? The arc-
cosine of the standing wave current magnitude above *IS* the
number of degrees of phase angle away from the feedpoint. Since
the antenna is an archetypical standing wave antenna, that phase
angle is also the absolute magnitude of the forward and reflected
current phase angles where those phase angles have opposite signs.

But the value of current at one point is *NOT* all we have
so your supposition is irrelevant. After a century of theory
by some of the most brilliant human minds, we know virtually
everything there is to know about a 1/2WL thin-wire dipole.
We know there *IS* indeed phase information in the standing
wave current magnitude just Kraus graphed it in his book.

> You need
> to compare it to something - itself even - somewhere or sometime else in
> order to have an idea of phase.

The standard thing to compare it to is the feedpoint current,
e.g. provided by EZNEC, usually 1.0 amps at 0 degrees.

> Here's what I mean: suppose I have a
> piece of wire of unknown length, excited by an unknown frequency, and
> picking a random point on the wire I measure 1.73 amps. What is the
> phase? You're trying to square the circle and hear the sound of one

First, you insult me with irrelevant ad hominem attacks ...

> Of course, in your
> case, you know the length of the wire, the frequency of the wave and
> its wavelength, and you think you know the current distribution
> on the wire (a half wavelength dipole) so you don't need anything
> but a ruler to find what you're looking for.

And second, you agree with Kraus and me ...

Here is a chart regarding Kraus' 1/2WL thin-wire dipole copied from
my other posting. Please tell us what is wrong with it and exactly
why the standing wave current magnitude doesn't tell us how many
degrees away the feedpoint is for the formula I = Io*cos(X).

X degrees away standing wave arc-cosine of the
from feedpoint current magnitude current magnitude
0 1.000 amps 0 deg
30 0.866 amps 30 deg
45 0.707 amps 45 deg
60 0.500 amps 60 deg
90 0.000 amps 90 deg

Do you really think it is a mere coincidence that column 1 and
column 3 are identical???

Now's your chance to enlighten us, Tom. Please explain again
how the standing wave current magnitude on a 1/2WL thin-wire
dipole doesn't depend upon how many degrees it is away from
the feed point, i.e. doesn't contain any phase information.

While you are at it, please explain exactly how Kraus is mistaken
about this antenna when he plots the standing wave current as
I = cos(X) where X is the number of degrees away from the
feedpoint and feedpoint current equals 1 amp at 0 degrees.

If it's one of those F connectors that use the centre conductor of the
cable as the 'pin' of the plug, the limit might be the quality of that
connection.

Is the wire short or long? Clean or corroded? Bent or straight? Does it
have a clean-cut end, or was it mashed flat? Who knows...

>I'd bet in the 200W range is not unreasonable.

Probably so... and probably more, if desperate enough. But reliability
is a different matter.

F connectors were designed for the cable industry, to be used by the
millions at the lowest possible cost. It doesn't seem like a good idea
to use such connectors in amateur radio, unless there is some other
compelling reason.

Yuri,

It seems to me that when "W8JI" is associated with something, you assume immediately that it is wrong. If you were to read Ronold W. P. King's explanation about small loop antennas in "Transmission Lines, Antennas and Waveguides", would you be any more apt to believe it? How about Glenn S. Smith's discussion of them in Johnson and Jasik's "Antenna Engineering Handbook" (second edition)? Each of those begins with a reasonably detailed description of an "unshielded" loop and moves on to a "shielded" loop.

In addition, can you expain to us how the current on the wires on the inside of the shield is NOT balanced by an equal current in the opposite direction on the inside surface of the shield? Please tell us in detail just what currents are where on the shielded loop. If you are going to try to tell us that some explanation is in error, please provide us with enough detail that we can make up our own minds. So far, all I've seen here is some vague reference to confusion about shields.

The descriptions in each of the two references I gave above are far more detailed than what you have posted here, either of your own or of W8JI's, and I find them both enlightening--they are slightly different from each other--but both detailed enough that you can make up your own mind about what's really going on, and not have to read ranting generalities or statements with nothing to back them up.

Cheers,
Tom

I didn't say that the value of the standing wave current on a
1/2 wavelength dipole doesn't vary with length. I did say that
just measuring the value at some point doesn't give you all the
information you need to calculate the phase. Of course, you already
know the phase, because you defined the antenna as 1/2
wavelength, so finding any kl is trivial. Secondly, even if you're
right about the current in your antenna being a sine function, in order
to use that information, you have to measure the current input at the
current maximum - which you've already defined to be the center of the
antenna - in order to compare it with the current at the point of
interest in order to get your result. In short, you still have to
know the current at two points in order to get an answer. The
information isn't contained in just one measurement. So let me turn it
around and ask you to tell me again why you think you can get some
"phase" information from measuring a single point on an antenna
without knowing anything else about it.

I haven't read Kraus, but I expect he was talking about an idealized,
infinitely thin antenna. Add thickness to the wire, and a feedpoint gap,
and you may come up with something slightly more complicated.

Apparently that knowledge is not enough for W7EL who said
regarding the current distribution in a 1/2WL thin-wire
dipole:

> W7EL wrote:
>> Of course I reject the notion that there's "phase information
>> in the standing wave current magnitude".

This in the face of technical evidence that the standing
wave current magnitude is a cosine function of the number
of degrees the referenced point is away from the feedpoint.

Also contradicting > Gene Fuller who said:
>> The only "phase" remaining is the cos (kz) term, which is really
>> an amplitude description, not a phase.

> By the way, where did you get that table, from EZNEC?

From page 464 of "Antennas for all Applications", 3rd Edition,
by Kraus and Marhefka. Where Kraus presents the independent
variable in fractions of a wavelength, I simply converted it
to degrees. Most knowledgeable people comprehend that there
are 360 degrees per sinusoidal cycle, i.e. per one wavelength.

Hi Tom,

Cecil probably doesn't understand that both options give both current
magnitude AND phase as choices. Rather makes the "question"
pointless, but nothing new in the correspondence from our Xerox
philosopher.

For the record:

____X____ Standing wave current magnitude contains NO phase
information.

The subject is a 1/2WL thin-wire dipole with a feedpoint current
of 1 amp at 0 degrees as illustrated by Kraus on page 464 of
"Antennas for All Applications", 3rd Edition. That's about the sixth
time I have stated those boundary conditions.

> The information isn't contained in just one measurement.

For a 1/2WL thin-wire dipole with a feedpoint current of 1 amp
at 0 degrees, as illustrated by Kraus, all the phase information
one needs to know is indeed "contained in just one measurement".

> I haven't read Kraus, but I expect he was talking about an idealized,
> infinitely thin antenna.

I have been very careful about specifying Kraus' 1/2WL thin-wire
dipole as the subject of this discussion. It is easiest to
understand because it has the least number of variables.

What is the agenda in trying to divert the subject away from
something easy to understand to something that is difficult
to understand?

Tom Donaly wrote:
> If a magnitude can, by itself, contain phase information, why
> do we have to specify the angle in a phasor?

The subject is the standing wave current phasor on a
1/2WL thin-wire dipole, not phasors in general.

The point is that we do *NOT* have to specify the angle
for the standing wave current phasor on a 1/2WL thin-wire
dipole. The standing wave current phase angle at any point
up and down the antenna is already known to be EXACTLY the
same as the angle of the source current at any particular
time. That's why W7EL's phase measurements were meaningless
and his conclusions false. Note he has refused to discuss
the subject with me here or over private email.

If the source current is 1 amp at 0 degrees, the standing
wave current magnitude equals cos(X) and the standing wave
current phase equals zero degrees. That you guys disagree
indicates ignorance of the assertions of Kraus, Balanis,
and others.

This is what the argument is all about. The phase angle
for the standing wave current is known to be zero degrees
and unchanging with respect to the source current phasor.
The standing wave magnitude is known to be the cosine of
the number of degrees away from the feedpoint. That same
number of degrees is the absolute value of the phase angle
of the forward current and reflected current phasors.

The magnitude of the standing wave current on a 1/2WL
thin-wire dipole, fed with 1 amp at 0 degrees as
illustrated by Kraus, indeed does contain all the phase
information that anyone could ever need or want.

Remember the context is the 1/2WL thin-wire dipole fed
by 1 amp at 0 degrees on page 464 in Kraus' "Antennas
For All Applications", 3rd Edition where the standing wave
current magnitude EQUALS cos(X) where X is the number of
degrees away from the feedpoint. The arc-cosine of the standing
wave current magnitude *IS* the phase.

One other point. At least one expert has said that nothing
is lost in the superposition process. We know that the
forward traveling wave has phase and the reverse traveling
wave has phase. If the superposed standing wave current
magnitude contains no phase information, then something was
lost in the superposition process because the standing wave
current phase certainly contains no phase information as
illustrated at:

Thanks, Alan. So the listing finally got changed -- people had complained, justifiably, that they didn't find me in the index. A couple of previous attempts to get it changed had failed, and I didn't realize it had succeeded this time.

Based on my reading, it appears that Kraus did not say anything closely resembling Cecil's comments. Cecil is "interpreting" a very simple picture in Kraus. All of the math appears to arise from Cecil's imagination.

Cecil is so good at quoting that he should have no problem with providing the exact unedited words from Kraus that support the arc-cosine analysis.

It looks like Cecil is trying to use "phase" as a function of position, of the envelope of a standing wave rather than the time phase of the total voltage or current which brings about the standing wave. This makes it possible to keep the simple topic suitably muddled and enhances the opportunity to misquote.

As I pointed out some time ago, the envelope of a standing wave isn't in general sinusoidally shaped. At the one extreme of a matched load, the total current or voltage vs position function is a straight line, and there is no standing wave. At the other extreme where there's a complete reflection, the function is sinusoidally shaped. The current on an antenna falls into neither category, although the distribution on a thin antenna is nearly sinusoidal. In between the two extremes, the shape of the total current or voltage vs position function (that is, the envelope of the standing wave) is neither straight nor sinusoidal, but can be described with hyperbolic trig functions.

You can of course divide the period of any periodic function into 360 degrees or two pi radians and call the point along it a "phase" relative to some arbitrary reference. In the case of a standing wave's envelope, doing so doesn't generally accomplish anything useful. But it seems to be providing fodder for imagining great and wonderful insights about physics. And it certainly is useful in keeping a meaningless argument going by interpreting "phase" to mean either time phase or the positional "phase" of a standing wave envelope as necessary to keep the discussion from proceeding on a linear and logical track.

you are great cecil, you cut out the original post to make it look like i had nothing to do with the original statement... if you will remember he was asking if he would get 25 ohms if he connected the braids together without the center conductors... i simply say that if you connect both the braid and center conductors you get a 25 ohm line... the implication being that if you don't connect the center conductors you don't get a 25 ohm line.

thanks for keeping the fight thread going so well, now that you are riled up i guess you can branch out into some other threads and bog them down for the rest of the week.

Sort of like what I have. Full size 75m loop fed at one corner. I connected a 1:1 current balun directly at the antenna , feeding a 1/4 wave section of RG11 Foam coax. All 50 Ohms downstream from there. SWR at resonance is about 1.2:1. No tuners.

You would expect the feedpoint impedance of a full wave loop (cut
using your formula) to be around 90 ohms at resonance.

You have then connected 25' of 450 ohm line. Lets assume this is
Wireman 551 line, the input impedance to this line section at
(assuming 3.7MHz) should be around 141+j282 (and line loss would be
~0.1dB).

You then have an unspecified length of "air dielectric RG/8" (new to
me) which will transform the impedance further.

You seem to intend to then use an ATU to transform this impedance to a
satisfactory load for the transmitter.

Where did you make the measurements with the MFJ269? If it was not at
the antenna feedpoint, did you really expect resonance at the
measurement point to coincide with loop resonance, and is resonance at
either point important to efficient operation of the entire system?

Owen

The new breed of compression type F connectors (T&B Snap-N-Seal) have
surprisingly good return loss up to 3 GHz and Canare advertises 26dB
return loss at 2GHz for their industry standard crimp type, see
http://www.canare.com/index.cfm?objectid=6994120C-3048-7098-AF9D73F542BECA48.
The female F receptacle usually has two fingers that grab the center
conductor and I think this would be the limiting factor in power
handling capacity.

True, I'm somewhat spoiled since I've always used fairly wide-range tuners.
Even my Intellituner will match a 64-1 load.

If you are looking for direct experience....

My M2 six meter Yagi's use F connectors and I regularly run 1000-1200 watts CW on six meters into one antenna.

The F connectors are in a coaxial feed for a T match, and the way they are configured each connector has half the line current but there is full line voltage on each connector. That's on six meters, and I mostly work CW (sometimes for a few hours straight).

I've used CATV hardline to F connectors for dipoles on HF many times. I used RG-6 style cable to feed dipoles for low bands, and the F connectors never failed even with high power.

I was a little scared of the RG-6 and F connectors on my M2 antenna feed system, but it has not been a problem. I never worried about 1500 watts at 160-40 meters and failure never was an issue. I high pot test F connector cable assemblies to about 2000 volts peak, so I expect current or moisture would be the limit.

Hi All,
I have a rotating Flag antenna. I'm rebuilding it so the horizontal
beam will rotate vertically. This will allow me to install new parts while
I'm standing on the ground. I hope this will make experimenting easier.
I have a pin that locks the beam 90 degrees to the mast. By drilling
another
hole I can make that any angle. Please see post "Flag Antenna Rotation"
in ABSE.
The question;
Is there any change in the pattern caused by tilting the Flag antenna?

Can someone familiar with Eznec run a case with the antenna
tilted 20 degrees from horizantal?

Thanks for any info,
Mike

Tom, whilst they are likely to withstand thousands of volts, small coaxial cables are unlikely to withstand the heat from the corresponding current if applied for sufficient time.

The focus in this discussion seems to be solely on the voltage withstand capability, whereas loss / ability to dissipate heat / temperature rise as installed are relevant and may be more constraining.

So far, so good. If the antenna is fed with 50 ohm coax, there will
be great losses, however, if I am correct, there will be negligible
losses with 450, or even less with 600 ohm twin-lead. A 2:1 balun at
the end of this 600 ohm wire should net a low-loss, but good match for
his antenna?

OK, I think that is a more technical explanations of what I said, so
we are in agreement. But for the sake of clarification, let me ask
this...

I have a yagi with about 25 ohms at the antenna. I connect 600 ohm
twin-lead and run it 1 1/2 wave lengths to my radio. This, I assume,
gives me the highest current at the end of the twin-lead. So I
connect it directly to the radio with a PL-259 and get an acceptable
load for the transmitter with low-loss in the feedline?

That's what might seem to you, but I point out gross misinformation, when I come across it. I express my opinion based on what I know or believe. I could be wrong and I gladly get educated. Mostly, if I see, measure or touch something, I believe it to be right. Mumbo-jumbo "scientwific explanation", taking off on tangent to justify the fallacy don't cut it with me.

> If you were to read Ronold W. P.

I don't have the King's book, in Jasik's the treatment of small loops and shielded loops is dealing with some "medieval" designs. The closest to my version is his Fig. 5.23a showing balanced shielded loop. But then the 5-23bdoesn't make much sense to me, having small loop on the front of reflector, when the small loop has the minimum of radiation along the axis through the loop, and he places the reflector in the minimum - null direction? The way they show the loops, half of loop solid wire, half coax line, creates confusion what is antenna, what is shield, or perhaps combines them. I have not used those designs.

> In addition, can you expain to us how the current on the wires on the

>
> Cheers,
> Tom
>

I will not get tangled into currents, phasors, but describe my design of small shielded loop antenna that I used on 160m and this should perhaps shed some light on the controversy.

I used 1/2" copper water tubing (non ferrous material passing the magnetic field) for circular loop about 4 foot diameter. At the top the loop had gap, at the bottom it was mounted in small metallic box. Loop, box and mast were all DC connected and grounded. Mast was about 5 ft high, with Ham-m rotor at the base to rotate the contraption. This formed Electrostatic shield for the antenna.

From the connection box I threaded three turns of electrical house wire #12 and across the ends connected mica trimmer capacitor C1 (abt 1200 pF?) to resonate the three wire loop antenna at 1.830 kHz). Not connected to anything else, nor ground or loop.
Then I threaded one turn of the same #12 wire as a coupling turn. One end was connected to the coax braid, the other end through another mica trimmer capacitor C2 to the center conductor of the coax. Floating, not grounded or connected to other loop or tubing.
I tuned the C1 to resonate the three turns at the desired frequency and C2 to provide 50 ohm match to coax. Circuit wise this mirrors the LC parallel tuned circuit with link coupling and provide better signal than other published designs.
I tried version of this without copper tubing shield and with. I had local AC power line noise (within fractions of wavelength) and shielded loop attenuated the local noise.
The way I see this works, the three turns were the antenna, it was tunable across the band. The "link" coupling allowed to keep the symmetry of antenna and provided some isolation for common mode currents between the antenna and coupling (well known in LC tuned circuit with link coupling.). The copper tubing was ELECTROSTATIC SHIELD which let's the EM waves pass through.
If the copper tubing IS the antenna, then how does it work? Short, grounded in the center bent dipole? Then the radiation pattern should have maximum perpendicular to the plane of the loop/dipole. But the antenna has NULLS in that direction, corresponding to the properties of the 3 plus 1 wire loops.
You scientwists can play games with theories how it should behave, but the reality again shows how it behaves. Anyone can build the antenna as I described and VERIFY it. Wire loops without electrostatic shield tubing still work the same way as with the shield. So which IS antenna?

Another description of the subject antenna is at
http://www.tpub.com/content/antennaandmasts/TM-11-5985-352-14/css/TM-11-5985-352-14_31.htm

"It is generally assumed that the current distribution of an
infinitesimally thin antenna is sinusoidal, ..."

Simply look at Kraus' graph in Figure 14-2. A sinusoid with
current amplitude equal to 1.0 at the center and current
amplitude equal to zero at the end is obviously a cosine
wave. Since the magnitude varies from 1.0 at the center to
zero at the end, taking the arc-cosine of the magnitude
yields the distance from the center in degrees.

Roy Lewallen wrote:
> It looks like Cecil is trying to use "phase" as a function of position,

Referenced to the source current, the phase of the forward traveling
wave current *IS* directly proportional to position along the dipole.
Any competent engineer knows that. So is the phase of the rearward
traveling wave current. That is obvious from the equations for those
two currents. Those are simply facts of physics that you probably
should try to comprehend instead of dismissing them.

Inet = Io*cos(X)*cos(wt) = Ifor*cos(-X+wt) + Iref*cos(X-wt)

Inet is the standing wave current. X is the distance in degrees from
the feedpoint. If the source current is 1.0 amps at 0 degrees, e.g.
from EZNEC, at t=0 Inet = Io*cos(X) = Ifor*cos(-X) + Iref*cos(X)

> As I pointed out some time ago, the envelope of a standing wave isn't in
> general sinusoidally shaped.

Balanis says: "If the diameter of each wire is very small (d << lamda)
the ideal standing wave pattern of the current along the arms of
the dipole is sinusoidal with a null at the end."

Kraus says: "It is generally assumed that the current distribution
of an infinitesimally thin antenna is sinusoidal,..."

d << lamda for an 80m dipole made out of #18 wire. I'm sorry to hear
that you disagree with both Balanis and Kraus.

I haven't gone through this in detail yet, but one misconception is glaring:

Yuri Blanarovich wrote:
> . . .
> I used 1/2" copper water tubing (non ferrous material passing the magnetic
> field) for circular loop about 4 foot diameter. . .

If you believe that, it's no surprise that you're having difficulty understanding how a shielded loop works.

It's not hard to demonstrate that the (time-varying) magnetic field doesn't penetrate a non-ferrous shield, if you believe (correctly) that a time-varying magnetic field will produce a current on a nearby conductor. Simply put an oscillator or signal source into a copper box -- you can solder one op out of PC board material. Run some wires all around the inside which carry the oscillator signal, putting them as close to the shield wall as you like. Put a battery inside the box to power the oscillator and seal the box up. Then sniff around the outside of the box with any kind of magnetic field detector you can devise. If you have a little potted oscillator of some kind, you should be able to do this in a couple of hours at most.

Or, just connect your rig to a good dummy load with some double shielded coax and sniff around the outside of the copper coax shield. If you put the detector just outside the shield, the current on the inside of the shield will be much closer to the detector than the current on the center conductor. So if the shield is transparent to a magnetic field, your detector should go wild. (Make sure the rig is very well shielded, though, so no common mode currents make their way from the rig to the outside of the shield.)

Alternatively, if you'll spend some time with a good electromagnetics text learning about eddy currents and the like, you'll understand why you'd be wasting your time with those experiments.

Once you're convinced that the shield blocks the magnetic as well as electric field, you'll have to revise your theory on how a shielded loop works. And you'll find that Tom's explanation is correct.

A 100 ohm antenna causes an SWR of 2:1 on 50 ohm coax. Lots
of hams don't even bother with a tuner when the SWR is 2:1. The
additional losses in 50 ohm coax due to an SWR of 2:1 are pretty
much negligible on 80m for reasonable lengths of feedline.

The SWR on the 600 ohm line will be 600/25 = 24:1

The SWR on 50 ohm coax will be 50/25 = 2:1

For a 25 ohm single band antenna, I would be inclined to go with
the coax.

What gets missed quite often in these discussions is that
everyone agrees on 99 44/100 percent of the technical issues
and we tend not to discuss those issues. We only discuss the
56/100 percent of the issues upon which we disagree. It is
akin to the arguments between Einstein and Bohr. I suspect
that no two people here on r.r.a.a are in 100% agreement
on everything.

Make no mistake about it, I disagree with everything Yuri has posted about the physics behind a "shielded loop".

I certainly don't want to be considered to be 99% in agreement with anyone who thinks a time-varying magnetic field can pass though a highly conductive copper wall, or any wall that is several skin depths thick, just as I don't want to be 99% in agreement with anyone who thinks a loading coil "replaces" or has the phase shift or "current drop" of missing electrical degrees.

The basic physical properties have to be understood before I'd be largely in agreement. If basic building blocks are wrong, our idea of how the worlds works must also be very distorted.

But Owen, I've used a variety of F connectors for hundreds of hours at
high power at lower HF and on six meters.

He asked if anyone had direct experience, and I stated what my first
hand experience with them was.

People would be amazed at the amount of power a good grade RG-6 style
cable will handle and how much power that F connector will take.

Tom, I agree with you. I use selected RG-6 cable myself, and it is greatly undervalued. But... my point was mainly, don't focus only on breakdown voltage, it is certainly a parameter that relates to instantaneous failure, but heat from losses (principally ohmic loss in the centre conductor) is an issue and may be more limiting. Of course, average power under typical voice SSB service is perhaps 2% of the PEP, so heat becomes less an issue than under higher duty cycle modes.

Discussion of F connectors inevitably leads to RG6. BNC connectors are readily available (at least over here) for RG6 and are my preferred choice.

HERE A FEW RESULTS:

QRV with RoomCap antenna on 80m

On May 15th, 2006 I was QRV on 80 m during 1 1/2 hour.
Tcvr: TS-50 (100 W PEP), QRG = 3.770 - 3.787 Mhz
Antenna: RoomCap with 1.66m radiator length
installed on my car. SWR = 1.0
QTH: Peripheral part of city of Basel.

Conditions: The band was weak with a lot of QRN.

Here follows the contacts and the
received signal reports:

20:10 DJ6YF, 59+10, Hans, Bielefeld
20:10 DL3EAI, 59, Reino, Mittetal (nr border to PA)
20:14 DJ6LGB, 58, Peter, L&#65533;neburg

The experiment I did years ago used a copper wall in a one or two foot square thin sheet.

I made a link on one side through a high power 50 ohm load resistor. This allowed me to run significant known current through the resistor (and link) from a regular HF transmitter.

Using two probes, one a sensitive low voltage dial light bulb with two prongs soldered on and the other a multiple turn loop with diode/meter indicator, I could roughly check current in multiple places on both sides of the sheet.

It was very easy to see where the magnetic field (and current) goes. It does not pass through the wall. It's quite amazing to see how even a direct soldered connection on one side will not produce current (and a magnetic field) on the other side.

That's part of the 56/100 percent of the issues upon which you
disagree.

> ... I don't want to be 99% in agreement with anyone who
> thinks a loading coil "replaces" or has the phase shift or "current
> drop" of missing electrical degrees.

Just proves that no individual is right 100% of the time. 75m
bugcatcher coils obey the laws of physics and thus suffer a
delay in the real world. Hint: Contrary to the lumped circuit
model, *everything* has a delay in the real world. The only place
coils don't have a delay is in your mind where miracles and
magic are possible.

The loading coil causes a phase shift in accordance with the
laws of physics. The stinger causes a phase shift in accordance
with the laws of physics. The impedance discontinuity between
the coil and stinger causes a phase shift in accordance with
the laws of physics. There are NO missing degrees.

When you comprehend how an electrical 1/4WL stub can be 19 degrees
of 450 ohm line plus 18 degrees of 50 ohm line and be physically
0.1 WL long, then you will have comprehended reality.

"1/2 wave of 75 ohm" would make matters worse for a 25 ohm
antenna since the SWR would be higher than for 50 ohms.
What you need is 1/4WL of 35 ohm coax like RG83.

Kraus is using author-speak as most technical authors do to
avoid nit-picking from people like you. Balanis uses the words,
"very small" for the wire diameter.

> I'm glad you clarified that for us. I was beginning to wonder about
> Kraus. Now I know it's just Kraus' message suffering from Cecil distortion.

It is true for infinitesimally thin wire *AND* anything close
to that condition, i.e. also true for d << lamda, according
to Balanis who says: "If the diameter of each wire is very
small (d << lamda), the ideal standing wave pattern of the
current along the arms of the dipole is sinusoidal with a null
at the end."

The diameter of #18 wire is certainly very small compared to
a wavelength at 80m (0.003' << 246') ensuring that the standing
wave current distribution on the real world dipole is sinusoidal
within a certain degree of real world accuracy.

If you want to see the sinusoidal current waveform for yourself,
observe the current distribution reported by EZNEC for a G5RV
used on 20m. Anyone with EZNEC, presumably including W7EL,
can observe that sinusoidal standing wave current pattern.

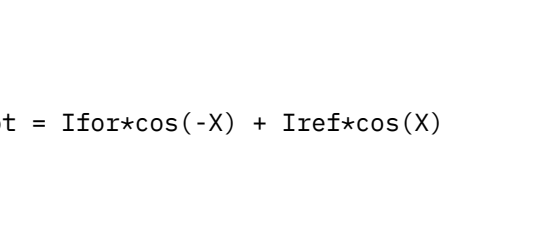
Quoting: "Figure 14-2 Relative current amplitude AND
PHASE along a center-fed 1/2WL cylindrical antenna."
Emphasis mine so you can't miss it this time.

I thought you were knowledgable enough to convert
Kraus's independent variable of wavelength to degrees in
his graph on page 464 of the 3rd edition of "Antennas For
All Applications". Allow me to assist you in that task.

The 'X' axis is "Distance from center of antenna in WL"

X in X in
wavelength degrees
0.00 0
0.05 18
0.10 36
0.15 54
0.20 72
0.25 90

Hope that helps you to understand Kraus's graph better.
Using the degree column, the standing wave current,
Itot, on that graph equals cos(X). The standing wave
current also equals Ifor*cos(-X) + Iref*cos(X) where
'X' is the phase angle of the forward traveling current
wave and the rearward traveling current wave. A phasor
diagram at 0.02WL = 72 degrees would look something
like this:



Incidentally, from the above phasor diagram, it is easy
to see why the phase angle of the standing wave current
is always zero (or 180 deg) since Ifor and Iref are
rotating in opposite directions at the same phase
velocity.

Roy wrote, "It's not hard to demonstrate that the (time-varying)
magnetic field
doesn't penetrate a non-ferrous shield, if you believe (correctly) that
a time-varying magnetic field will produce a current on a nearby
conductor."

Yes, it's all easy to demonstrate. It's used in practice all the time:
the shielding in a transmitter, the aluminum shield cans around IF and
RF coils, the copper strap around a power transformer (used
specifically to lower the external magnetic field around the
transformer, so it won't couple into low-level audio circuits or affect
colors on a color CRT).

And indeed it all agrees with theory. For this one, you need little
more than Faraday's Law of Magnetic Induction.

It's fine with me if there are people who don't want to be bothered
with theory, but if they profess that something works by means
different from the theory that I understand and which agrees with the
observations I make, they shouldn't expect me to believe them without
putting some very serious effort into explaining why the accepted
theory is wrong. I believe Yuri when he tells me his antenna works.
But I'm not buying into his explanation of HOW it works.

Cheers,
Tom

I only know about an 'offline' ARRL modelling course
(http://www.arrl.org/catalog/?item=8721).
It's based on EZnec, NecWin+ and/or 'pure' Nec2 models. You can also
use 4nec2 to run the models. From my memory: mostly HF, some VHF/UHF
and no microwave.

Arie.

I encourage Yuri to add this experiment to the ones I suggested, or just do this one. Understanding what happens to the currents and fields in the presence of a shield is essential to understanding "shielded" loop operation, and his statement about magnetic fields and non-ferrous shields shows that he lacks this understanding. Any explanation based on the mistaken idea that a non-ferrous shield is transparent to a magnetic field is bound to be seriously flawed.

Could you explain how to build one of those antennas that has infinite
impedance at its ends?

NEC does not have any specific frequency limit -- see FAQ
www.nittany-scientific.com
"What is the frequency limitation of NEC?

There is no limit on the frequency range although NEC is usually not used
for frequencies above 2 GHz.

NEC is dependent on the structure geometry not the frequency. If the
structure can be modeled following the NEC guidelines then the appropriate
frequency can be used."

If the ARRL "On-line" Antenna course (See Arie's link above) is anything
like Cebik's two books (Available at Nittany Scientific) then I would
strongly recommend it.

Frank

Give it up, Cecil. You don't even have a coherent notion of the
meaning of the term "phase." Selectively quoting, and re-interpreting
Bibles in order to make it seem as if the Gods agree with you won't cut
it, either. All the simple-minded rural sophistry in the world won't
make you right, or the rest of us wrong.

I noticed, I did not read the link I supplied well enough. There also seems to be an online course. I presume it's based on the same book and model-files.

Concerning the frequency-limit, I know there are a number of 2.4 ghz wlan Nec2 models published on the internet and for myself I once modeled a 11 ghz satellite dish using both surface patches and a wire-grid. However I can not say very much about how well these models agree with the real world counterparts.

Arie.

Small mobile antennas (in terms of wavelength) aren't generally very
efficient. The above test only shows you can make contacts. It
doesn't address efficiency or field strength in relation to
a similar, but larger antenna. Have you put the plans online
for this thing, or are you just using them to augment your
net worth?

I am not selling explanations how it works.
I understand your and Roy's points. I am not claiming to try to formulate the infinitesimal theory of wasaaaap and I didn't try that with loading coils. Ensuing discussions helped me to better understand the mechanaism of how things work, the theory and how can I better apply them. I thank you for that.

What I have problem with someone claiming shield is not a shield (Why do they bother calling it shield or shielded loop?), when I saw the shielding properties of it in the vicinity of the local interfering signals. It performs as a shield to the antenna that is wound inside. Tom categorically denies SHIELD, it IS the ANTENNA he claims. (Like there is no current drop along the loading coil! - The gospel from the all-knowing guru.)
What I have problem with someone claiming the small loop antenna (three plus one turn) is not the antenna, but when I remove the shield, the "not

antenna" is still THE ANTENNA.

I am not arguing the mechanics or theory behind how the shield works, it may be transparency to magnetic field, it may be the voltage generated in the gap, bla, bla...
Based on my experience with the said antenna, I concluded that wire loops are THE antenna, shield works as an electrostatic shield.

I know that if I stick oscillator inside of 10' of 1/2" tubing, I will get hardly or no signal out. I know if I bend that tubing into a circle with gap and stick wire loop antenna inside, I can get signals out of that "shielded" antenna and can attenuate close by interfering signals. Shielding doesn't MAKE my antenna work (it works without shield too), shield enhances its rejection/shielding properties in near fields.
I know there are small loops and there are small shielded loops and they work and I have proved it.

Just don't tell me it is called shield because it is antenna, or that antenna inside the shield doesn't work, or shield doesn't shield from electrostatic fields, or that my antenna I described doesn't work as I described.

Tom may pontificate his ideas to his worshippers, but I don't swallow that. I point out my, and who else cares, disagreement, especially when I see his "ideas" migrating into ham literature.

Go ahead with your but, but, butts.....

depends on the height of the reflecting/refracting layer, time of day,
sunspot number and associated geometry. Intensity of signals will depend on
how the radiation angle - pattern of the antennas fits the propagation
angles.
There are some propagation programs that will provide good answers based on
above data.

==========

The type of antenna or its radiation pattern has nothing whatever to do with the path taken by the radio wave through the ionosphere. The take-off angle and its name, generated by EZNEC, can be very misleading.

The radio path is simply a matter of trigonometry involving only the groundpath distance between transmitter and receiver and the height of the reflecting layer.

The height of the reflecting layer changes between day and night. And there may be more than one layer present in daylight. The layer actually used depends on frequency.

If the Tx and Rx stations are far apart, the trigonometry becomes a little bit complicated because of the curvature of the Earth's surface. But for groundpath distances up to 500 miles a flat earth can be assumed. Get a sheet of paper and a pencil and sketch the triangle to be solved. The average height of the F-Layer in darkness is about 200 miles. In daylight it is about 300 miles.

To do the actual calculations download program SKYTRIG from website below in a few seconds and run immediately. SKYTRIG is near the bottom of the list on the "Download Progs From Here" page. Just left-click on it.

I've had many EZNEC users tell me they thought the course was very worthwhile.

As others have mentioned, there's no upper frequency limit to NEC or its derivative programs, but some of the geometries used at microwave frequencies don't lend themselves well to NEC modeling. I've done considerable modeling with EZNEC at 6 GHz and found the results to be satisfactory.

I learned about shieldings, Faradyas, I use them, in equipment design, in RF and harmonics suppression, I built shielded room for university. But I also know the difference between the Farady shield and Electrostatic shield and seen them work. Maybe lumping all shields is as no good as lumping all coils ain't no good?

Roy,
I have magnetothermia machine which is about 200 W push-pull power generator at around 27 MHz. It uses single turn, shielded loop, made of coax, about 30 inch in circumference. Loop wire, antenna (center conductor of coax) is fed from the plates of two tubes, shield is open at the far end and grounded at the exit from the enclosure. I get those 200 W heating my body tissue with magnetic field. Maybe it has something to do with shielding being a fraction of a wavelength distance from the radiator and the properties of the magnetic and electric components in the antenna reactive near field region?

I know that this loop radiates along its circumference, not just from the gap in the shield. What's yer theory? Or it don't (ooops, can't) woyk?

You seem to associate and stick to wrongos and I am sorry you find their explanations correct, for the reality proves them wrong.

If you are referring to EC-004, I took the course last fall.

I went into it knowing I was pretty antenna smart already. I deserved the humbling experience. As with most endeavors, if you have a lot of self discipline you could do fine just buying the book and some modeling software. If I had not taken the course, I would not have stayed on track. It was well worth the effort and the expense. The course uses Nec-2 or EZNEC. I opted for EZNEC+ mainly because I was able to try out the demo version. I have never regretted it and I have not felt the need for NEC-2.

I feel it has saved me a lot of frustration in dealing with my own antennas. It is not specific to any frequency or type of antennas. It provides you with the information on how to evaluate plans without having to suffer some mistakes. It also provides warnings about where modeling fails. I think it is worth both the time and money.

2541. End Fed Zepp Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2006-05-16 17:21:03 UTC
From: gsm@mendelson.com
Message-ID: <slrne6k1v3.n5v.gsm@cable.mendelson.com>
Source record: 59383

I was browsing the MFJ online catalog and saw an "End Fed Zepp" antenna.
It looks like it would fit nicely in the space I have. I'm in Israel,
so the hassle and expense of ordering ones make we want to try to build it.

I've seen some writeups on end fed zepps, which were a short wire on the
"ground" side and a longer wire on the "hot" side. The MFJ looks like
a long wire on the "hot" side and a matching network made from a piece
of 450 ohm ladder line.

It looks like the ladder line is hung from the center insulator and the
coax is connected to the middle (figuratively) of the ladder line. The long
wire is connected to the "hot" side and the "ground" side is not connected,
but used for an insulating support rope.

Anyone have any ideas, specs, or web page references?

Thanks,

Geoff.

Source record: 59384

Yuri,

Just once, and I'm done with this.

Someone somewhere along the line mistakenly called it a shield. They didn't understand how it works and what's important. Get over it. Look at just the "shield" with no wires inside. Isn't that exactly a single turn loop antenna? Isn't the feedpoint the gap in the loop?

If you put a wire (or several wires) through the inside of that tube you used to call the shield, they just pick up the signal from the feedpoint. Consider a single wire through the tube. There is a voltage across the gap, the feedpoint of the loop. Since there is essentially no voltage drop along the wire in the center, across the distance of the gap in the tube, then the voltage across the gap must appear as transmission line voltage across the coaxial feedlines which are made up of the wire and the inner surface of the tube. If you've arranged things symmetrically, then the total gap voltage will divide equally between the two. Then it's just standard coaxial lines from there to where you connect your receiver, or where you put a tuned tank.

Or if you have multiple wires through the tube, the net transmission line current divides among them. And you can resonate them with a capacitor, but that doesn't make them have antenna currents on them.

If you have another way to analyze it accurately, fine. I don't care. My way works for me, and it does not disagree with the _performance_ I've seen you post about. It does disagree with the _theory_ you've suggested.

As for WHY adding the "shield" helps get rid of local e-field noise (from sources less than a few wavelengths away, which at VLF might be kilometers), and why the nulls are more perfect, it's because symmetry is CRITICAL for that performance, and adding the outside tube allows you to make a more perfectly symmetrical loop than you can practically accomplish with just wires and all the tuning stuff you hang off it. If you are VERY careful to keep things symmetrical, you can also do it without the tube. But it takes amazingly little imbalance to screw things up.

Dat's it in a nutshell.

Cheers,
Tom

An open circuit is close enough to infinite to satisfy
almost anyone. In virtually every technical textbook,
ideal conditions are assumed until one understands the
concepts involved. Then the real world conditions are
introduced. That's all I am doing - presenting the
concepts involved in an ideal dipole as described by
Kraus and Balanis. Do secondary real world conditions
exist in reality. Of course they do and nobody is
saying that they don't. The difference between infinity
and ten megohms is often negligible for analysis purposes.

Dear Mr. Dixon (AC7ZN):

I took the course. What a bargain! Though antennas are one of my areas, I found the course interesting. It also gave me first hand experience with "distance learning." Many Universities will be increasing their offerings using this scheme.

Unfortunately, the grammar and syntax of the presentations suggests that the work has not been proofread. Professor C's work suffers now and again from what must be transcription errors. A small number of the exam questions have a wrong right-answer.

Even with a few warts, I recommend taking the course.

When you lose the technical argument, Tom, you always respond
with ad hominem attacks devoid of any technical content.

Fact is, the phase of the forward traveling current referenced
to the source current is equal to the distance from the source
expressed in degrees. The laws of physics will not stand for
anything else. That same number of degrees *IS* the phase
angle of the traveling wave(s). Every competent engineer knows
that as it is obvious from the equations in any good textbook.

That chart is in the ARRL Antenna Book. Assuming F2 layer
reflection, the arriving angle is reported to be in excess
of 50 degrees.

It looks like a standard single band Zepp to me. It has
a very high feedpoint impedance which the 1/4WL of
ladder-line transforms down to the neighborhood of
50 ohms. There will be some feedline radiation. Please
note MFJ's admonition: "REQUIRES BALANCED LINE ANTENNA
TUNER OR TUNER/BALUN"

But Tom's explanation is correct. It's consistent with theory; alternate explanations aren't. If you're really interested in learning how a "shielded" loop works and won't accept Tom's explanation because it came from Tom, you can find a similar explanation in a number of reputable texts. I'll gladly provide references, if you ask before I leave for Dayton. Once you gain an understanding of some basic electromagnetic principles, the correctness of the explanation will be obvious.

Oh, and don't worry about Tom's ideas migrating into the literature. They were already in the literature well before any of us were born.

Cecil,

I don't understand why you complain about Tom D. You do exactly the
same thing all through any discussion.

On the QRZ forum you have post after post edited by moderators, that's
something that almost never happens! It's all on QRZ for people to see.
The list moderator even made a very rare public appearance to directly
warn you about your style.

It's pretty tough to have a non-personal technical discussion with you
because you distort facts and resort to the very same ad hominem
attacks you dislike from others.

Why not set a good example rather than yelling about Tom D.?

Cec, there you go again, quoting the bibles!

If the F2 is present then it must be daylight.

And if its daylight then the E-Layer must also be present.

For a groundpath distance of 400 miles the most likely reflector is
the E-Layer. In daylight the E-Layer is an excellent, stable
reflector. Furthermore, the radio path distance is considerably
shorter than via the higher F1 or F2-Layers.

The height of the E-Layer is about 70 miles.

Assuming a flat Earth, the elevation angle is -

ArcTan(70/200) = 19 degrees.

It depends to some extent on the E-Layer critical frequency and the
MUF. If the MUF is low enough and the transmit frequency is high
enough, e.g., 14 or 21 MHz, then the wave may pass right through the
E-Layer and be reflected most likely by the F1-Layer at a height of
roughly 300 miles.

Signals received via the F-Layers, if received at all, will be weaker
than via the E-Layer, if only because the path length is greater.

The elevation angle via the F1-Layer will be about -

ArcTan(300/200) = 56 degrees.

At night the E and F2 layers disappear. There remains only the
nighttime F at a height of about 200 miles to give an elevation angle
of 45 degrees.

That is, of course, if the nighttime-F critical frequency and MUF
allows propagation. There are such things as skip distances.

(Roy, no, I havn't made arrangements with high power broadcasters at
known distances to make tests to prove the foregoing predictions. And
yes, I know it's refraction and not reflection.)

Reg, G4FGQ.

Cecil,

I don't know why you go through all of these gyrations. The phase shown by Kraus is durn close to zero. Everyone else who has joined in on this thread agrees; there is no meaningful phase characteristic for a standing wave. Your last sentence above says the same thing.

It seems you simply like to argue, even when there is no disagreement. Perhaps you need a dog to go with your hog. 8-)

Hi Geoff,

It's a standard end fed Zepp (The Zepp was designed as a single band
antenna , but will work with varying degrees of performance on other
bands as well. it's quite simple 1/2wave flatop endfed with open wire
line 1/4 wave (figure the velocity factor in) must be fed with a
balanced tuner. they can work quite well but there will be some feed
line radiation , that's not always bad. see the following write up
http://www.cebik.com/gup/gup12.html

> ain't no good?

Sorry, you're not making much sense to me. You said that a non-ferrous shield is transparent to a (time-varying) magnetic field. The experiments I proposed illustrate that this is false. This has nothing to do with what name you attach to a shield.
>
> Roy,
> I have magnetothermia machine which is about 200 W push-pull power generator

> magnetic field.

Hm. How do you know it's from just the magnetic field?

This is really interesting. Just a couple of postings ago, you said that a non-ferrous shield is transparent to a magnetic field. Now you say that a magnetic field is heating your body. Do you have some embedded steel shrapnel or something making your body ferrous, or do you just eat lots of nails and scrap metal?

Maybe it has something to do with shielding being a fraction
> of a wavelength distance from the radiator and the properties of the
> magnetic and electric components in the antenna reactive near field region?

What has? The heating? That's due to the lossiness of bodily fluids in the presence of either time-varying magnetic or electric fields.

> I know that this loop radiates along its circumference, not just from the
> gap in the shield. What's yer theory? Or it don't (ooops, can't) woyk?

If you'll read what Tom has posted, or a description in any good text, you'll find that the whole circumference of a "shielded" loop radiates. The field comes from current on the outside of the "shield", not from some field penetrating the shield. That's my theory. It's the same as Tom's, and that of every respected author I've read.

> You seem to associate and stick to wrongos and I am sorry you find their
> explanations correct, for the reality proves them wrong.

Reality proves Newton wrong -- any fool can see that moving objects come to rest on their own. There's no conflict between theory and reality -- just between theory and people's interpretations of what they're seeing.

I'll stick with the theory that's been known and confirmed for over a century. People with alternate theories, like yours, will have to provide some extraordinary proof to sway my thinking.

It seems you're more interested in proving Tom to be wrong about something -- anything! -- than taking the effort to really understand what's actually happening. So nothing else I can post will help you. I hope the lurkers have gotten something from this, though.

Glenn, and others- Have the text book for this course, and it costs
$39.95, + shipping (think $7.50), and it is fairly comprehensive,
several hundred pages (1 inch thick)!, and has 31 lessons, +
appendices, and the answers to the questions in the lessons.
It's ISBN # is 0-87259-872-1 . If you sign up for the course,
this manual is available, in .PDF format (have lots of ink and paper!)
as a download! Unfortunately, had other things come up, so didnt get to
even start the course, but from what in in the textbook, it is more than
worth the money! Well worth the money if you have EZNEC, or other
varieties of NEC. Wish had the ambition to try it again. Think it would
be better than most of the Leagues antenna books, for reference purposes!
Here is the Table of Contents:
Familiarization with antenna modeling
The language of modeling
Setting up an antenna model
Antenna model outputs
Model sources
Model grounds
Frequency selection, sweeps and scaling
Antenna loads
Transmission lines
Antenna model adequacy testing
Workarounds for NEC-2 limitations
Modeling by Equation
Practical modeling
Advanced and specialized modeling
...and more.

Hope this helps, Jim NN7K

Ah, the "it works because I made contacts with the following DX"
antenna argument.

This may be an extremely compelling way of measuring performance of an
antenna system if done correctly.

It's certainly the most compelling kind of marketing argument snagging
prospective "magic antenna" buyers, especially those who don't have
another antenna up for comparison. But is there a way to make such an
anecdotal claim and have it mean something?

I'm thinking something along the lines of probability of making contact
with a station with identical equipment, averaged over a very very long
time.

If you know the statistical ionospheric loss for the path, the power
levels involved, and antenna gain (or LOSS) you can calculate such a
thing.

I've heard an argument recently that a particular antenna system must
not be too inefficient because it was able to produce contacts with
stations in Australia and New Zealand. The data below are in the same
category.

How do you know that the RoomCap antenna contacts were not made because
the stations on the OTHER END have much MUCH better antennas?

The dynamic range of signals present on the amateur bands is enormous.
You could have an antenna with a gain of -35dBi and still make regular
contacts. That doesn't mean it's good. How about if we stick to dB
gain relative to some simple reference antenna or the isotropic for
antenna reporting?

Don't get me wrong, you can have tons of fun with a bad antenna. I'm
sure that all the great DX I can work with my 100 feet of magnet wire
at 30 feet is largely due to the stations on the other end, and if
you're doing the best you can given the limitations of the situation,
then you're holding up your end of the DX bargain.

I worked 9M2CNC the other day on 17m with my antenna system! Does that
mean I get to sell it for $190 to suckers? Or does it just mean that
the propagation was good, the station on the other end was good, and
I'm managing to not turn all of my 100W into local heating?

73,
Dan

Diameter tolerance or out of round? It's probably not too big of a deal for most applications especially if you're going to split/slit and clamp it.

You're probably better off erring on the side of slight interference if you're splitting and clamping and adjustability is not very important.

If you're looking to make a sliding adjustable joint, I'd keep a nice tight tolerance, maybe no more than a few thousandths of an inch if you can do so. If you can't, it's not a big deal, but a good mechanical fit will allow sliding while still giving lots of strength.

If you make the fit loose (>10 thousandths) you're going to be relying on your hose clamps or bolts to do all the holding and you're probably going to really only get contact under the clamping points, which is OK in a lot of applications. A better fit will spread out the clamping force more.

> That is, of course, if the nighttime-F critical frequency and MUF
> allows propagation. There are such things as skip distances.
>
==========

Simplified Critical Frequencies, MUF and Skip Distances.

At a vertical elevation angle of 90 degrees, the Critical Frequency is that frequency above which the radio wave passes right through the layer and is not reflected.

It may be reflected back to Earth by a higher layer if there is one. If the critical frequency of the higher layer is not high enough then the wave may pass through that layer too and be lost forever.

Critical frequencies are generally at the lower HF frequencies and depend on geographical latitude, the angle of the sun, time of day, winter or summer, and on the state of the sun. That's why Near Vertical Incidence transmissions are at low frequencies in the 80m and sometimes in the 40m bands and are uncertain.

As the transmit elevation angle changes from vertical, the angle of incidence of the wave with the ionospheric layer becomes less than 90 degrees and frequencies greater than critical begin to be reflected.

The Maximum Usable Frequency (MUF), that is the highest frequency which is reflected, is aways higher than the critical frequency. It is given by MUF = Fcrit/Sin(Phi) where Phi is the angle of incidence of the wave with the layer. The MUF can be several times critical frequency - conditions which occur at very low transmit elevation angles.

This explains how best DX is obtained on the 15m and 10m amateur bands at the height of the sun-spot cycle when critical frequencies are at their maximum but still relatively low. Nobody points their 10m beams up into the sky to work DX. Very low angle radiation is called for. Yagi beam booms are horizontal, pointed at the horizon.

The lower the elevation angle of the radio path the higher is the MUF. There is a skip distance. At distances less than the skip distance nothing can be heard. This is because the operating frequency is too high. It is greater than the MUF and the wave passes through the layer without reflection. The lower the operating frequency the shorter is the skip distance. Eventually, at MF, there is only Near Vertical Incidence radiation and groundwave.

I trust the foregoing makes sense.

There is a short table of typical critical frequencies in the notes
attached to program SKYTRIG. They have been collected over the years
from various sources. MUF = Fcrit/Sin(Phi). To find Phi use the
program. It's only trigonometry.

Just stumbled on this item, indicating that youze guyz might be defficient in more areas and I should revise my treatment of some of your previous answers.

from Johnson - Jasik, Antenna Engineering Handbook, 2nd Ed., p. 5-21:

"The brevity of this review requires omission of many interesting topics concerning loop antennas. In recent years, there has been considerable study of loop antennas in close proximity to or embedded in material media such as the ocean, the earth, or a plasma. The electrical characteristics of loops in these instances can be quite different from those of loops in unbounded free space, as described in this review. The major applications of this work are in the areas of subsurface communication and detection (geophysical prospecting).
The loop antenna near a planar interface separating two semi-infinite material regions, such as the air and the earth, has been investigated extensively. When the loop is electrically small, it can be approximated by an elementary magnetic dipole, and the electromagnetic field away from the loop can be determined from the classical analysis of Sommerfeld. If the field near the electrically small loop is required, the approximation by a magnetic dipole may no longer be adequate, and a loop with a finite radius and a uniform current must be considered. For the electrically large loop near a planar interface, an analysis that allows a nonuniform current in the loop, such as the Fourier-series analysis for the circular loop, must be used."

So this idea goes into "to do" pile to be researched or explored.

Hi Yuri,

Just so you get to that first instead of 'splainin' it.

You might visit the library for a copy of R.W.P. King's "Antennas in
Matter," of which I have a copy. You've gotten the short answer from
us, the long answer doesn't change the outcome.

NEC-4 is a lot less expensive than it used to be, and it can be used to analyze antennas immersed in water, dirt, or another medium besides air.

As for the complexity of calculating the near field, you can struggle through the math as suggested by Jasik, or you can let EZNEC do it for you and get the answer in seconds. EZNEC makes no simplifying assumptions about the loop size.

Roy Lewallen, W7EL

-Proud to add the title of Yuri "defficient" to my many others. Not quite the level of being a Reg's Old Wife, but a credit nonetheless. Thanks, Yuri!

A multi-band doublet may in itself not be exactly resonate so
transmission line's length resonate length may not be a factor.
Normally - in typical ham style - use the length of line necessary to
make from you antenna to your transmitter (or antenna tuner). If you
encounter difficulties tuning and a few feet to your transmission
line.

Message-ID: <KO-dnQI0UrIw-ffZnZ2dnUVZ_tKdnZ2d@crocker.com>
Source record: 59416

diameter tolerance is what i am looking for. this is an antenna element joint with 2 through bolts in the swaged area, no slitting. measured diameters are 1.252 OD for the inner piece and 1.264-1.277" ID for the swaged section, slightly out of round because of the 2 bolts flattening it a bit. the bolts are vertical and when tightened 'normally' which causes a bit of flattening, the element can move horizontally quite a bit. any recommendations for improvements?? adding horizontal bolts? shims? any portable tools to swage something that big, or is that a machine shop only type of job?

ok, a 100 ohm load fed with 50 ohm coax is a 2:1 swr. Fed with 75 ohm
coax, it is 1.33:1 ??

If the 75 ohm is fed with 50 ohm coax 1/4 wave down the 75 ohm coax,
it will be a close match?

Why did the impedance change to 52 ohms?

Because of the energy bouncing back and forth between the 100 ohm load (that mismatches the 75 ohm, so causes a reflection) and the 50 ohm feed (that mismatches the 75 ohm section, so causes a reflection).

If the 1/4 wave section has an impedance that is the geometric mean of the impedance on each end, it creates a perfect matching resonator.

So the perfect 1/4 wave matching section between 50 and 100 ohms would have an impedance of the square root of (50 times 100) or 70.7 ohms. 75 is pretty close.

Dear friends,

I am very well aware of what you mean.
Read my part "Evaluation of HF Antennas" on my homepage
and then, the many comparisons of the RoomCap with
many other, well known antennes, which were made
side on side, also found on my page.

I think, the real comparitive results is the only one that counts
for an antenna.

With best 73s

Surely you jest... :) Fight! Fight! Fight! Kinda reminds me of
Beevis and Butthead after eating too much chocolate..
K7ITM pretty much boiled it down to the raw minerals by
noting that the usual "shielded loops" only advantage is the oft
improved balance. I've already been through all this mess testing
them here...
And I've proven to myself that an open wire loop can be just as
good as a "shielded loop" just as long as balance is taken care
of. It's the balance that matters. If the two types are equally
balanced,
and the same size, they will act the same.
The rest is just fodder for bored old farts on a newsgroup.
Of course, many won't agree with me, and this would include Yuri,
since he believes a shielded loop is quieter than an open loop.
But I don't care.
It's a free country. Or I think it is... Sometimes I wonder these days

with all these goofballs we have in DC running the show.

With a multi-band, center-fed, doublet, forget all about resonant frequencies of both antenna and line and take the 450-ohm line (or preferably 600-ohm) from the antenna all the way to the shack with a little bit extra.

You will need a choke balun and tuner at the shack end. And you will never have a more efficient arrangement.

Reg.

Yes, and 75/1.33 = 56.25 ohms. For a perfect match to 50
ohms, one would need Z0 = SQRT(100*50) = 70.7 ohms.

> If the 75 ohm is fed with 50 ohm coax 1/4 wave down the 75 ohm coax,
> it will be a close match?

The SWR on the 50 ohm coax will be 56.25/50 = 1.125:1

> Why did the impedance change to 52 ohms?

It didn't. It changed to 56.25 ohms. The load is 100 ohms
and the Z0 is 75 ohms so the SWR is 1.33:1 at the current
minimum/voltage maximum point. To find the impedance 1/4WL
away, divide Z0 by SWR, 75/1.33 = 56.25 ohms.

I think what the original poster is trying to avoid is a
voltage maximum, current minimum point at the transmitter.
For instance, that 25 ohm antenna fed with 600 ohm open-
wire line would present an impedance of 15K ohms at the
transmitter when the feedline is an odd multiple of 1/4
WL long.

Assuming that you are trying to avoid feeding the antenna
system at a current minimum point, the free demo version
of EZNEC will do that for you.

There's a DOS program on my web page at:

http://www.qsl.net/w5dxp/imax.exe

that will give the approximate feedline length for
feeding the antenna system at a current maximum
point.

==========
But that might occur at only one frequency in the range 1.8 to 30 MHz
and the probability of it falling in an amateur band is remote.

If it should fall into an amateur band and its on his favourite
frequency then all he has to do is change the feeder length by a few
feet.

Statistically he can't lose.

Reg.

So I would cut my feedline to an odd multiple of a quarter wavelength of
the lowest band I intend to use?

In my old 1960 ARRL antenna handbook (Ninth edition) they tell me to add
one half of the dipole plus the length of the feedline then go to a
chart, figure 3-50 p. 107, which shows various lengths that would be ok.

This stuff gets confusing when there are so many different ways that it
is explained.

The information in the arrl antenna handbook you are quoting above is
for center feeding resonate (or near resonate) 1/2-wave dipole with
coax transmission line.

You are describing a multi-band doublet. That antenna is seldom
resonate on all bands (if any) and you are using open ladder
transmission line to feed it. Resonance is not an issue in this case.

Just put up the anenna, feed it with enough transmission line to make
to you shack. Should you encounter a problem matching with you tuner
then just add a few feet to the transmission line and be done with it.

Danny, K6MHE

No, your antenna is probably not 25 ohms as in the example.

> In my old 1960 ARRL antenna handbook (Ninth edition) they tell me to add
> one half of the dipole plus the length of the feedline then go to a
> chart, figure 3-50 p. 107, which shows various lengths that would be ok.

There's a DOS program on my web page which will give the
approximate lengths for optimum feedline lengths:

http://www.qsl.net/w5dxp/imax.exe

For instance, that program says 58 feet and 89 feet are
good lengths for feeding a 102 foot dipole on 14.2 MHz
with 450 ohm ladder-line. Halfway between those two lengths,
i.e. anything around 74 feet, should be avoided for 20m.

More information on feedline length for a 130 foot dipole
is at http://www.qsl.net/w5dxp/notuner.htm

The free demo version of EZNEC will also yield this kind
of information.

It is hard to look at a radiation pattern, conclude that the take-off angle is the only angle of radiation, and then blame it on EZNEC! Most of the antennas that I have modeled seem to have radiation in lots of directions. 8^) Otherwise you are correct.

I'm fairly ignorant when it comes to shielding. Do the
magnetic fields from a magnet penetrate copper? Do the
magnetic fields from 60 Hz devices penetrate the shield
on coax?

> type of job?

Dave,

The easiest fix would be to add one or two more bolts in the horizontal direction. The resulting shape of the outer element would be slightly squared, but that should not cause any problems. Thin shims would be a nuisance.

There are portable tools used for swaging. In particular, people who make boilers for model steam locomotives often use a swaging process to fit the boiler tubes tightly into the end plates. The key for any sort of portable or hand-held swaging is that it is much easier to expand the smaller tube than to shrink the larger tube. The metal needs to be soft, however, and useful aluminum antenna elements would generally be a bit hard. Since you need only a few mils, it might work.

Assuming the source signal is sinusoidal, your above assertion
would require non-linearity in the antenna. Since antennas are
generally considered to be linear systems, would you please
explain where the nonlinearity is coming from?

You said there is phase remaining in the cos(kz) term which
is contained in the amplitude.

Then you said there is no phase information.

Those statements contradict each other.

In any case, the graph at

http://www.qsl.net/w5dxp/travstnd.GIF

proves that there is phase information contained in the
standing wave current magnitude. The arc-cosine of the
standing wave current magnitude is identical to the phase
of the traveling wave referenced to the source current.

Please note that the "experts" have been strangely silent
on the contents of that graph.

Additional thought: Assuming the source signal is a pure sine
wave, if the standing wave current "isn't in general sinusoidally
shaped", then the antenna would have to be introducing harmonic
radiation that doesn't exist in the source signal. That fact is
easily proved with a Fourier analysis.

I wasn't aware that standing wave antennas cause radiation on
harmonic frequencies. Any standing wave current waveform that
deviates very far from a sinusoid would be illegal.

OK, so it's aluminum, and I'm talking about antenna models, and, well, I could make the claim that the roof is "hot" with RF because of induced currents... but... the question:

I've got a mast that can get my VHF/UHF antennas up above the roof of my apartment building about four feet, above ground about 28 feet. My balcony has a ceiling made of aluminum, so I've got this big metal sheet (about 16 feet x 8 feet) close by under the antennas. I want to use EZNEC to model the effect of the whole system, antenna above ground and at the corner of this big aluminum sheet.

I figure a grid is OK if the mesh is fairly fine (what, maybe .1 wavelength?) but the problem is that I'm going to run out of segments. Even if I upgrade to EZNEC+ and get 1000 more segments, I may not have enough to do a 16 foot by 8 foot mesh. I've tried a close spaced set of parallel wires and ignored the segmentation warnings and I see some reasonably sensible pattern distortion, but I wonder if anyone could point me to some tricks to make a relatively coarse grid of wires seem like a plane. Will fat wires help?

Sooo, in shielded loop the shield is the antenna according to W8JI and worshippers. But you take the shield (W8JI antenna) away, now the wires are antenna, some say don't need no stinkin' shield and "antenna" to work as an antenna.

> The rest is just fodder for bored old farts on a newsgroup.
> Of course, many won't agree with me, and this would include Yuri,
> since he believes a shielded loop is quieter than an open loop.
> But I don't care.

Amazing how selective in reading and digestion of postings some people are. They tend to ignore the reality and description of it, they pick on selective "proof" of what they were taught and figered out.
I emphasize, that electrostatic shield on the loop antenna is effective on close proximity radiation, within some fractions of a wavelength from the source of interference/signal. It does not (significantly) affect band noise or distant noise/signals. Anyone who can build shielded loop and test it within local arcing source or test transmitter, can see the attenuation of the said noise.
So shield works as a electrostatic shield, if you guys like it or not, or refuse to admit.
It is not that I believe in that, I have experienced it, seen it, measured it and it works, it is there and anoyne can verify that, contrary to "theories" of those who "figured" it can't be.
Electrostatic shields work on principle of capacitance plate, being grounded and side exposed to electrical/electrostatic fields shunting the field to ground. Capacitor's one "plate" is the interference/signal source (antenna) - other "plate" is the el. static loop shield, grounded, shunting electrical fields to ground and preventing from entering the antenna. (Something like that).

Sooo, antenna works without shield (not just my assertion), but when you insert it in the shield then shield becomes W8JI antenna. So his shield, untuned becomes antenna, but my tuned and tunable inside the shield antenna is not the antenna? Makes as much sense as "there is equal current along the loading coil doesn't matter what", riiiiight?

It has to do. It allows us to direct the RF under desired angle to hit the layer or region that supports the propagation to the chosen target.
I have seen situations when signals to Europe were coming under low angle and in the same direction, signals to deep Asia were coming under higher angle at the same time.

There are different propagation modes and paths and be able to control radiation pattern of antenna is important (for serious hams, like contesters). I am not talking about skewed path, long path and other modes of propagation when horizontal and vertical control of the antenna radiation pattern is of huge benefit.

So making blank statements like above is not proper.

There's a very simple test of this "shield." It relates to experience
and doesn't need for you to go to the library.

1.) Tack a wire across the gap.

Q. Do you still have signal?

A. No!? None????

Extra Credit Question:
Did the wire make the "shield" better, or worse?

73's
Richard Clark, KB7QHC

p.s.
from your experience, the answer to the initial question above may
vary. If in fact it does, it may bring new material for discussion.

Before you pronounce your verdict, why don't youze guyze build the shielded loop antenna as I described and test it. Try version without shield, see what IS antenna, and try the same antenna with shielded loop. Then run electric drill or another source of arcing or interference in the vicinity and see if there is shielding effect or not. Then pronounce your verdict and pontificate on how electrostatic shields suppose to work. Otherwise you look silly like W8JI cult worshippers.

Agree!
That makes it Faraday shield, which stops any signal from entering inside of the tubing.
I never asserted that Faraday shield or closed metallic enclosure passes any signals or fields.
We are talking about electrostatic shield, which if removed, antenna works without change, you put it back, it still works the same way plus it rejects in its reactive near field region electrical field interference.
If it was to be antenna, then when removed, the rest should stop working as an antenna, or what is the theory?

> Extra Credit Question:
> Did the wire make the "shield" better, or worse?

It turned it to Farady shield and prevented signals from exciting the antenna inside.

Extra Credit Question for professor:
Q1: If electrostatic shield is added to small loop antenna and it attenuates the interference or signals from its vicinity, does it perform the function of a shield or antenna?
Q2: Can the piece of tubing that is grounded by its outside surface, acts as a capacitor's plate and provide the path to ground for electric field in vicinity?

I just wish that points of discrepancy were addressed, rather than parties taking off on tangents fitting their convinctions and trying to weasel out of the wrong statements.

No it wouldn't, Cecil. Even you know better than that. For those who believe Cecil, consider a lossy transmission line terminated in a short, or open. The signal is attenuated as it goes down the line, and also attenuated as it comes back up the line, in an exponential fashion. The envelope is thus not sinusoidal. The signal may be sinusoidal, but the envelope can't possibly be. Cecil's antennas may be lossless, but most of us want our antennas to radiate energy, hopefully, as efficiently as possible, so we have to put up with current distributions that aren't easy either to envision or to calculate. That's why even Cecil uses EZNEC.

That is only the indication that antenna works.

The REAL comparative results are the measurements done on the test range and compared to antenna that you claim to be as good or better.
Another indication of performance would be to model the antenna in question vs. "standard" like full size vertical.
Another meaningful test would be to compare RoomCap antenna to another efficient mobile antenna like TexasBugcatcher or Screwdriver, on the same car, taking field strength measurements.

If it is so good as you claim, normally one would apply for patent and make millions by selling it. Claiming miracles and asking for money to find out what it is, is fishing for fools.

Hams are (or were) known to be honest, gentlemen and willing to share their ideas with others for advancement of our art. Looks like lately we have influx of "magicians" claiming to outperform real antennas with some miniatures. So far no winners!

Good Luck.

Cecil, W5DXP wrote:
"Assuming the source signal is a pure sine wave, if the standing wave current "isn`t in general sinusoidally shaped (as Roy said)", then the antenna would have to be introducing harmonic radiation that doesn`t exist in the source signal."

Standing waves are produced by forward and reflected traveling soinusoidal waves produced by the same generator. Coherent signals on a transmission line and antenna of the same frequency are correctly represented by phasors.

The term phasor is preferred over vector for an arrow which indicates phase separation and magnitude of an electrical unit. Phasors are used to represent sinusoidal voltages and currents. They are also used to represent reactances and impedances.

Like vectors, phasors can be "added" by the head-to-tail method or by the component method.

If a phasor represents an alternating current:
I = Io cos omega t,
then the sum of the two phasors representing forward and reflected sinusoidal components is another sinusoid of the same frequency.

Point is the components are amenable to phasor representation. All the old authors do it. This amenability is proof the standing wave is a sinusoid too.

Best regards, Richard Harrison, KB5WZI

Yuri,

But you can't "direct" it.

You have to do your best with whatever elevation angle Eznec dictates.

Reg.

It's still the same "1/2 inch copper water tubing (non ferrous
material passing the magnetic field)."

So, does that wire make the "shield" better, or worse?

Super-extra credit question:
If we replaced the non ferrous material (same gap, no link) with (most
have probably anticipated this) a ferrous material, does this allow
near field region electrical field interference to pass un-impeded?

An attenuated (damped) sinusoidal signal is still sinusoidal, Tom.
The fact that such a signal doesn't generate harmonics proves
that it is sinusoidal. If it were not sinusoidal, it would
by definition, be generating harmonics. Are you really asserting
that a damped sinusoidal signal generates harmonics? That's the
only way to prove it has gone nonsinusoidal.

All non-sinusoidal waveforms contain harmonics of the fundamental
frequency. Every competent engineer in the world is aware of that
technical fact. If the source signal to an antenna is a pure single-
frequency sine wave, and if the standing wave current is non-
sinusoidal, then the antenna has necessarily introduced harmonics,
i.e. the antenna is non-linear.

W7EL is simply mistaken when he says the standing wave current
waveform is not sinusoidal. If the standing wave current waveform
ever was nonsinusoidal, the antenna would, by definition, be
non-linear and be generating harmonics not present in the source
waveform.

Seems you guys need to review your Math 202 course covering Fourier
transforms.

The absence of harmonic frequencies generated by the antenna
is also proof that the standing wave is a sinusoid. All
nonsinusoidal waveforms contain harmonics.

In spite of W7EL's assertions that antennas generate nonsinusoidal waveforms, they indeed are linear and bear a striking resemblence to a lossy transmission line. Why do you think they are called standing wave antennas?

Take a look at page 18 of Balanis' "Antenna Theory", 2nd edition, Figure 1.15. He shows how to turn a transmission line into an dipole with exactly the same standing wave current distribution before and after.

"Even morte amazing is that they (antennas) are linear transmission lines."

Antennas and transmission lines are linear, passive, and carry incident and reflected waves in much the same manner.

Look at "Current Distribution in Wire Antennas" on page 866 of Terman`s 1955 edition of "Electronic and Radio Engineering":
"A wire antenna is a circuit with distributed constants; hence the current distribution in a wire antenna that results from the application of a localized voltage follows the principles discussed in Chapt. 4---."
Chapt.4 is entitled "Transmission Lines".

> an antenna, or what is the theory?

Yuri,

A shield is a shield.

People made some very good posts explaining how the "shield" works, and there was nothing wrong with my original explaination.

You stated the shield is an "electrostatic" shield and I pointed out a static field does NOT cause noise. Static is by definition stationary or non-varying.

The only reason the shield affects the noise, as I and others have pointed out, is the shield changes the balance of the system. The shield IS the actual portion of the antenna that receives the signal, whether that signal is noise or an intentional desired signal.

The entire shield can be dispensed with without any change in the system so long as the system remains in balance, and that is quite possible to do.

As a mater of fact if a non-symmetrical "shield" is added over a balanced system it will decrease balance and make the system more susceptable to noise because the feedline will become part of the actual antenna.

You might look for a copy of "Fundamentals of Electricity and Magnetism" (McGraw-Hill). This entire book deals with basic field behavior and entire chapters explain in detail what everyone is saying.

As Roy pointed out, I didn't make this stuff up. It has been in print since the 1800's and the electric field effects first experimented with around 600 BC (although it was the 1600's before serious experiments were done).

There's nothing impossible about what you may have observed but the reasoning you gave and statements about my explaination being in error

are wrong.

There is absolutely nothing that causes noise to electric field dominant and the shield absolutely does not "filter" the time-varying electric field from the time-varying magnetic field. The shield IS the actual antenna and the stuff inside it, once inside it, is excited only by the gap. Nothing at frequencies of interest passes through the shield walls.This is a very well-known behavior and why so many immediately disagreed with your description.

Hi Richard,

I note you do NOT say "in exactly the same manner," which is unsupportable in the literature. So, when you abstract from antennas to
>Chapt.4 is entitled "Transmission Lines".
it is apparent that to a first approximation, and for the purposes of illustration (not engineering, except for amateur purposes) that it may seem to be so.

Of course, all things are possible when the limits of Cecil's error band encompass ï¿½59%. Even White can be darn dark.

==
Yuri,

The elevation angle of the radio path from the transmitter on its way
to the target changes with the number of hops.

How does Eznec know the number of hops? How does Eznec know which
angle is correct? How does Eznec know the height of the reflecting
layers? How does Eznec know the distances at which the radio wave
returns to Earth to be re-reflected?

Eznec doesn't know. And neither does the radio operator unless he
estimates everything AFTER the event.

Radio waves follow paths dictated by trigonometry and geometry and are
entirely independent of the idiosyncrasies of radio antennas.

Reg.

Yuri, you is way too intense! I don't pontificate, and my silliness is
genetic, not involved in any worship of W8JI.

I very much expect that any effects that you see may be due to another
cause than what you attribute it to. I don't know if your antenna is not
completely shielded along it's entire circumference or not. I wonder if
you could put your antenna inside a Faraday cage and see different
results. Perhaps even try the unshielded antenna in the Faraday cage.

Unshielded antenna in cage should equal shielded loop in open. If it
doesn't, I'd look for a problem in the experiment first, not a problem
in the theory.

We're talking about the envelope, Cecil, what are you talking about?
Since you've become so enamored of math all of a sudden, go ahead and

plot the current envelope on a length of very lossy transmission line
and tell me, with a straight face, that it follows a sine
function. On the other hand, don't bother. I know it's too hard
on your head, but it's an interesting exercise for everyone else.

Hi Richard,

It is one thing to run a Xerox, it is another to apply it to one particular howler that has Yuri stumped:

Super-extra credit question:
If we replaced the non ferrous material (same gap, no link) with (most have probably anticipated this) a ferrous material, does this allow near field region electrical field interference to pass un-impeded?

Either transmission lines are linear or they are not linear.
The only way for them to generate nonsinusoidal signals is
for them to be nonlinear. The same goes for antennas.

The envelope of an unattenuated sine wave is a straight line, Tom.
Is a straight line sinusoidal? Give us an everloving break! You
can fool half the people half the time but please stop trying to
fool all the people all the time.

Here is an example that should put an end to your foolishness.

100W-----50 ohm coax------50 ohm load dissipating 50 watts

Please explain how the 3dB attenuation in the coax causes
nonsinusoidal signals in the system. Proof of nonsinusoidal
signals would be the generation of harmonics. We are all
awaiting your reinvention of the laws of physics.

Tom, W8JI wrote:
"There is absolutely nothing that causes (sic) noise to electric field dominant and the shield absolutely does not "filter" the time-varying electric field from the time varying magnetic field."

A "Faraday shield" is designed to allow magnetic field coupling while disallowing electric coupling. See page 38 of Terman`s 1955 edition:
"It is possible to shield slectrostatic flux without simultaneously affecting the magnetic field by surrounding the free space to be shielded with a conducting cage that is made in such a way as to provide no low-resistance path for the flow of eddy currents, while at the same time offering a metallic terminal upon which electrostatic flux lines can terminate."

I`ve previously described the Faraday picket fences or Faraday screens used in the medium wave broadcast stations where I worked that were used to avoid capacitive coupling to the antennas while permitting magnetic coupling. Capacitive coupling would favor harmonics of the operating frequency. These are undesirable. The Faraday screen effectively rejects the capacitive coupling. It shorts the lightning strikes to ground too.

In a Faraday screen one end of pickets or wires is grounded. Their other ends are open-circuited. So, circulating current can`t flow through the wires. Thus, no counter-field can be generated to oppose magnetic coupling but capacitive flux lines land on the wires and are shorted to ground. It all works very well.

Look at Terman`s shielded loop on page 1048 of his 1955 editiomn. There`s a gap in the shield opposite the feedpoint. The gap prevents current circulation in the loop shield thereby making it permeable to magnetic coupling while shorting the electric field to ground. Therefore, this loop cover is a Faraday screen.

Why should we care if noise comes from near or far? The near field has 3 components. See "TV and Other Receiving Antennas" by Arnold B. Bailey.

The first near field component is produced by the electric vector and decays by the cube of the distance. The second is the induction field and decays as the square of the distance. The third is the radiation field electric vector which becomes the volts per meter at a great distance. This decays inversely with distance and its power decays as the square of the distance. 6 dB every time the distance doubles.

Point is we don`t have to get very far from a noise source to make a big improvement in noise received, especially if we avoid electric field coupling which decays especially fast in the near field.

Best regards, Richard Harrison, KB5WZI

> rewritten with corrections.

If you read what has been said here very carefully you will find Yuri claims the shield "blocks electric fields" or stops "electrostatic fields". This is the effect of a Faraday cage or shield.

I did not claim that effect. Terman certainly did not. It is a folklore or Ham-myth that only appears in amateur circles.

What others (including Terman exactly as you quoted) are trying to tell Yuri is the shield ONLY affects balance. The shield IS the actual antenna element that does the radiating. That is written in a half dozen engineering good engineering references. That is how ANY shield behaves.

Read here:

http://en.wikipedia.org/wiki/Faraday_cage

or here:

http://members.aol.com/omlcgm/detecknowledgy/faraday.htm

or any of dozens of other places. Unless an off-the-wall hobbyist publication or rouge opinion, you will see everyone agrees.

What Terman said is absolutely correct. The "shield" (when properly constructed) balances the capacitance of the antenna to earth. It does not "stop" the electric field. It certainly does not filter a time-varying electric field because doing so would by definition of Maxwell's equations (which everyone who isn't a CFA or EH antenna quack agrees are true) also stop the time varying magnetic field.

As everyone (including Terman) has tried to explain, the shield only affects balance. The shield HAS to be the actual antenna element because by definition of ALL the peer-reviewed textbooks published to date as well as any description of coaxial cables the inner shield wall is isolated from the outside by the skin depth of that wall.

This is so very simple to prove, it only takes a moment. It doesn't even take exotic test gear. These experiments were done in the 18th century with very crude instruments.

You can take a solid copper sheet for example and place a small loop antenna near that "wall". If you probe current on the wall near the

loop on the loop side, you will find a current maximum right under that loop. VERY easy to see. 100% repeatable.

Now if you move the probe to the other side of the wall you will find current MINIMUM at the sheet center and increasing towards two of the edges.

This is a TOTALLY open wall with no seal, it isn't even a box.

Shields a few skin depths thick are a virtually perfect barrier to both magnetic and electric fields. This is true for densely woven coaxial cable shield or even thin aluminum shields, metallic sheets, or any good conductive wall.

Saying Terman supports anything to the contrary only proves someone is misquoting or misunderstanding plain English, since Terman is a very clear writer. There is no way Terman failed basic physics and his peer reviewed textbooks are wrong.

Yuri may need to read some basic textbooks, I'd be happy to copy the applicable pages if there isn't a good library nearby. It is essential to get the basics down solid.

You bet I can, I can do that with stacked antennas, rotatable, polarization switchable, phasing, crank up tower changing height antennas - and by what antenna design and surroundings dictate, not EZNEC. EZNEC gives approximate picture of radiation pattern produced by antenna model. Real life (ground conditions, surroundings) changes the antenna pattern.
So I would be carefull giving EZNEC absolute powers dictating anything :-)
Combined with terrain analysis software, it will give better picture of where the antenna projects the signal.

The ionospheric propagation is not that clear cut simple, it is very
complicated. We have reflections going on and we have refractions going on
in the media that is like stormy sea. With the same height layer, and
uniform conditions, you can have more hops under higher launching angle, or
you can have fewer hops under lower angles. There could be another higher
layer with more complications of ducting or "bouncing" between the layers.

> How does Eznec know the number of hops? How does Eznec know which
> angle is correct? How does Eznec know the height of the reflecting

> returns to Earth to be re-reflected?
>
EZNEC knows sheeet about propagation. EZNEC and other antenna modeling
software can calculate the radiation pattern of modeled (not real) antenna
according to given ground parameters and antenna geometry. It gives you idea
how the pattern looks, but not the where the signal goes after entering
propagation media.

> Eznec doesn't know. And neither does the radio operator unless he
> estimates everything AFTER the event.
>

I know based on my experience operating at various times in the sunspot cycle and my knowledge of propagation. There are now quite good propagation programs that based on propagation indices and flux numbers, can give rough idea where is the bulk of propagating going. Extreme antennas can do one better, propagate where software doesn't think you can.

> Radio waves follow paths dictated by trigonometry and geometry and are
> entirely independent of the idiosyncrasies of radio antennas.
> ----
> Reg.

Very fuzzy trig and geometry, it is not polished mirrors out there, it is fuzzy bunch of ion-clouds like "hamburgers" that do their thing massaging the signals. By using antennas that have stearable pattern, vertically and horizontally one can take advantage of various modes of propagation. So it takes natenna "idiot syncracies" to dictate where the signal goes, and how it will propagate, conditions permitting.
See my article on "conducting" way back in CQ Magazine
http://members.aol.com/ve3bmv/bmvpropagation.htm

Richard,
thanks for the reference and support, coming from one who had his hands
"dirtied" with the antennas.

Terman also says just a sentence before:
"Errors from unbalance can be minimized by using circuit arrangements
that are symmetrical with respect to ground, such as shown in Fig. 26-27b.
It is also helpful to enclose the loop in an electrostatic shield, such as
metal housing broken by an insulated bushing, as show schematically in Fig.
26-27c."
and then sentence quoted above.

Clearly, the shield is functioning as an electrostatic shield, providing
symmetry and is not acting as "W8JI Antenna". Loops are the antenna, shield
is the SHIELD, contrary to W8JI proselytizing.
Small loops are the antennas, with or without the shield. Electrostatic
shield is a shield, provides symmetry for the antenna and helps to reject,
shunt the interference from the sources in the proximity of the antenna by
its virtue of the capacitance to the ground.
Terman didn't say: "yo stupid, you don need no stinkin' loops, jus' use the
shield as antenna" :-)))

Tom, W8JI wrote:
"I did not claim that effect. Terman certainly did not. (Yuri claims the shield "blocks electric fields" or stops "electrostatic fields".)"

I`ll requote Terman from page 38 of his 1955 edition which Tom ignored:
"It is possible to shield electrostatic flux without simultaneously affecting the magnetic field by surrounding the space to be shielded wih a conducting cage that is made in such a way as to provide no low-resistance path for the flow of eddy currents while at the same time offering a metallic terminal upon which electrostatic flux lines can terminate."

That is a description of the shield on Terman`s direction finding loop. The loop has a gap in the shield opposite its feedpoint. The gap prevents current from circulating around the loop shield and thus prevents creation of an opposing magnetic field by the shield to the incident field acting on the loop.

The grounded shield nevertheless terminates electric flux shorting it to ground.

The loop shield is thus a true Faraday screen, not a Faraday car body or screened room.

Best regards, Richard Harrison, KB5WZI

Of course it will not work, Faraday cage - shield, shields all RF.

> Unshielded antenna in cage should equal shielded loop in open. If it
> doesn't, I'd look for a problem in the experiment first, not a problem in
> the theory.

It is electrostatic shield, not "shielded, closed" loop shield. Antenna will still work the same inside the cage, just will not receive any signals if they are not passed through the cage. I am not overthrowing legitimate theories, I am describing what I observed and objecting to call the shield an antenna, when it isn't!!!

> - 73 de Mike KB3EIA -

I have no problem with theories, I have problem with silly claims that shield is an antenna. I described my experiments, explained behavior and performance of the shielded loop in the near field interfering signals/noise.
Build it, if you have problem with local noise, you would see the benefit of the electrostatic shield on the suppression of it and on symmetry and deep nulls on other signals. Shield is a shield and not antenna. Rest of mumbo-jumbo is twist away from the subject and attempt to legitimize wrongoooo!

Nice try, but you still keep conflating time with distance.
If any of the lurkers on this newsgroup want, they can
consider a dipole somewhat shorter than 1/2 wavelength. According to
one of Cecil's sources, Balanis, the current distribution on such
a wire resembles a triangle. Now, it's true you can do a Fourier
analysis on this triangle, but you won't come up with frequencies.
You will come up with an infinite group of sine and cosine waves
with units of cycles/meter (as opposed to cycles/second). What earthly
use are units of cycles/meter? Does Cecil have a radio that can tune in
cycles/meter? On the other hand, if you could measure the current and
turn it into a voltage so an oscilloscope could show it, you would see
a nice sine wave everywhere except at the ends of your antenna. And the
units would be in cycles per second. Cycles per meter, phaseless
phasors... you sure have a vivid imagination, Cecil.

Richard.

I know anything Roy Lewallen agrees with, you disagree with. I know anything I say (or even what I don't say) sets Yuri off into a foaming lather. I really wish you guys could put personal hate or dislike aside and look at facts. This is an imporant issue because the myth about shields is imbedded in amateur circles despite many clearly written engineering texts and very simple experiments that prove the concept of time-varying magnetic fields penetating the shield. It's just a fact when the time-varying electric field is taken to zero so is the time-varying magnetic field.

Static by definition is not moving or varying. Don't confuse jargon describing a different coupling mode with the mechanics of a loop operating at radio frequencies.

When we receive noise or signals, the fields are time-varying. Just as with a piece of coaxial cable, the inner wall of a "shielded loop" is isolated by the skin depth of the conductor from the outside wall. The electric and magnetic coupling effects are what causes a coaxial cable with a dense shield more than a few skin depths thick to ALWAYS have the same current on the inside of the shield as the inner conductor has, and all radiation or common mode current flow over the outside.

This isn't something I invented. It has been in nearly every textbook long before I was born.

I'm pleased that Yuri credits me for the work, but unfortunately I had little to do with it. It really was people from the 1700's and 1800's that did all the work.

You (and Yuri) appear to be confusing how time-varying fields work.

I suggest you put Terman aside and actually read some textbooks on fields.

It's helpful to actually make a few measurements. A few minutes spent with some very simple test equipment would go a long way to "turning on the light".

> The loop shield is thus a true Faraday screen, not a Faraday car body or
> screened room.

If you say so. And as one, it also must block any time-varying magnetic field. As K7ITM points out it is the gap in the loop that is actually the feedpoint, and it is the outside of the loop that is the actual antenna.

If you do not think a loop behaves this way, you need to get busy doing some real important work. You need to get all the Handbooks to quit talking about common mode currents on shield outsides. You need to get them to quit treating the inside of the shield as a isolated conductor that is independent of the outside.

As I and others have suggested it only takes a moment to prove the books are correct. You can prove it with a single sheet of copper and a minimum of test equipment.

>Felix HB9ABX

Felix, first of all, there needs to be a comparison with other
antennas over a number of different days with different conditions.
Secondly, I can't believe 59 reports from DX stations (I know, this
puts you into a handicap situation.) The problem is that many DX
stations will report 59 and ask you to repeat your call or name a
hundred times. The test really needs to be handled in an antenna
shootout of sorts. I have a 20 meter hamstick on my car and I often
get 59 reports from dx as well as CONUS stations. When band
conditions are well, I can get a 59 signal from a qrp rig. The real
test of the antenna will be with comparing the reception and reports
with the weakest stations. It takes a tremendous power change to
change a strong signal's report.

Additionally, you claim to be the creator of this antenna. This is also a problem since you are trying to profit from it's plans. You don't have calibrated or calculated gain/loss, bandwidth or radiation patterns. What's to say your antenna is any better than the grasswire antenna if you haven't compared them?

> According to
> one of Cecil's sources, Balanis, the current distribution on such
> a wire resembles a triangle.

It only resembles a triangle. It is actually part of a
cosine waveform. From cos(80) to cos(90), the cosine
function is close to a straight line but it is *NOT*
a straight line. Assuming the current distribution is
a triangular is only an approximation with a known error.
The current distribution acutally remains a cosine function
but assuming a straight line simplifies the math and doesn't
cause an unacceptably large error.

It is akin to the approximation that A = sin(A) when
A is very small. It is *ONLY* an approximation with limited
accuracy.

cos(80)=0.17365, cos(85)=0.08716, cos(90)=0

0.17365/2 = 0.08682 which is an error of 0.4% when one assumes
a triangular function.

Do you remember the antenna that came out in the middle to late 70's?
It was a dipole antenna with a specially designed cobra-head that
tuned it to any HF frequency. The SWR was virtually flat across all
bands from 160 meters to 10 meters regardless of the length of wire.
No tuner needed! Several companies bought one and tried to
disassemble them. The result was always a mess of broken parts.
x-rays were fooled by the number of parts, but someone was successful
in taking one apart and yet leaving the actual connected parts of the
antenna together. It turns out the antenna was nothing but a 50 ohm
resister surrounded by many useless, broken parts frozen in the epoxy
used to seal and hide the true design of the antenna.

I wonder if that genius is still alive and well?

I have heard of many hams stacking beams vertically to get that
earlier signal on one beam, and later in the day, the other beam gets
the stronger signal. Together, they still amplify the signal, but
sometimes one does much better than others at the TOA.

Reg, what were you drinking when you wrote this? EZNEC doesn't deal
at all with the atmosphere, it deals with the antenna. If the antenna
has a stronger lobe at 10 degrees in some given direction, EZNEC plots
it, but that doesn't mean the signal will come from that direction.

I have done only a little modeling with the ARRL version and the newer
free one. EZNEC plots the angles of the antenna from a horizontal and
vertical standpoint. Some antennas create single or double, primary
lobes, and others have more primary (highest gain) lobes. However,
when you change the elevation angle that you are watching, those
primary lobes may change to a different angle.

Tom, W8JI wrote:
"This is an important issue because the myth about shields is embedded in amateur circles despite many clearly written engineering texts and very simple experiments that prove the concept of time-varying magnetic fields penetrating the shield."

Some of that poison reached the 2006 ARRL Handbook on page 13.18. Fig 13.26 says:
"Electrostatically-shielded loop for RDF. To prevent shielding of the loop from magnetic fields, leave the shield unconnected at one end."

Terman`s RDF loop should have better balance than ARRL`s because Terman`s shield gap is squarely in the center of the loop and not at one end. However, as long as the shield is broken preventing induced current from flowing around the shield, Lenz`s law will be thwarted and magnetic coupling to the coil under the shield will be obtained. Electric field coupling to the coil beneath the shield will be disallowed by the shield`s connection to ground wherever it occurs, though not as elegantly as when care is taken to get the best balance possible.

I`ve worked with such Faraday screens in my broadcasting career.

Best regards, Richard Harrison, KB5WZI

>worshippers. But you take the shield (W8JI antenna) away, now the wires are
>antenna, some say don't need no stinkin' shield and "antenna" to work as an
>antenna.

I don't know what a W8JI antenna is, except for those I've heard on
160m... :/
But I do know that I've tested various versions of both shielded and
unshielded
loops, and have never been able to tell a lick of difference as far as
close local
noise pickup. I spent a whole week testing that very thing. It's not
something I just
made up, or picked up from W8JI.

>Amazing how selective in reading and digestion of postings some people are.
>They tend to ignore the reality and description of it, they pick on
>selective "proof" of what they were taught and figered out.

Only my test results were used to come up with my conclusion. So I
guess
I taught myself. I've never built a shielded loop yet that was any
"quieter" to
local noise than any of my good unshielded loops. But my unshielded
loops
are well balanced. Were yours?

> So shield works as a electrostatic shield, if you guys like it or not, or
>refuse to admit.

I refuse to admit it, if I can't prove it. And I haven't been able to
prove it yet.
One thing...How in the heck is a solid shield going to filter one
source of RF,
and ignore another. In reality, it will shield *all* RF, unless I am
missing
something here. So the outer shield *must* be the antenna, unless the
sky is
now green. No RF is going to prevail past the outer skin depth of the
solid
shield. None. Nada...

>Sooo, antenna works without shield (not just my assertion), but when you
>insert it in the shield then shield becomes W8JI antenna.

It does? I'm sure if this is the case, it probably tunes 160m.... :/

So his shield,
>untuned becomes antenna, but my tuned and tunable inside the shield antenna
>is not the antenna? Makes as much sense as "there is equal current along the
>loading coil doesn't matter what", riiiiight?

If you say so....

>Let's stick to some reality in antennas.

Thats all I do. I've made a load of loops. I have a diamond loop 44
inches
per side right next to me. Almost is as tall as the ceiling... Heck, I
even
have tried using shielded loops as the coupling loop to unshielded
loops.
Works pretty well to maintain balance, but mine work just as well with
just
a simple unshielded coupling loop. Probably cuz my loops are very
symmetrical
and balanced naturally. The coax feedline itself is the only real issue
in my case,
and even it's not really very critical. I never saw any indication
that using a
shielded coupling loop made the loop quieter than not using one. Not
once.
Myself, I don't really like small loops for receiving on 160m. They are
good for
cutting the noise when working loud locals, but in my experience they
are
pretty ho-hum when receiving weak dx. For 160m, I would use the biggest
loop
I could manage. Probably outside to have enough room...
My loops are mainly for MW BC receiving, although the one next to me
tunes
500-2300 kc in two stages, by switching cap gangs. I can go LW if I
tack on
more fixed caps. The real value of small loops are not the "quiet", or
the s/n
or whatever. It's the nulls... But nulls have much more value in the BC
band,
than they do on 160m unless maybe you have a noise source in the area
you wanna null out. Thats how a loop reduces noise. Using the nulls...
:/
I do have to agree with Tom. I think the "shielded loop" theory many
hams
adhere to is just another batch of wive tailery.. Along with grounds to
cure
antenna/feedline problems, sticking coax ends in bottles hoping to
thwart
lightning, etc... And I've never once talked to Tom about small loops.
It's all my idea to shun this "shield=quiet" theory, not W8JI's.

It looks like he is now selling it as an antenna tuner.

Not accounting for his marketing technique, his idea wasn't all bad.
I found a 100 ohm, 300 watt resistor when I worked for George at
Disc-Cap electronics, a surplus sales company. It was heavy, but I
wired it across the two legs of an 80 meter dipole and got less than
1.5:1 anywhere I tuned the transmitter. It was lossy compared to a
resonant antenna, but it worked ok. I would love to have one again.
In an emergency, you can't get the wrong length of antenna wire, even
no wire gave a good match and would probably radiate 100 watts at
least as well as some QRP stations ;). Of course one needs to HEAR the
station they are talking with sometimes....

I would love to compare the results of using that with the t2fd.

I would amend Cecil's statement to:
'We hope antennas are linear systems.'

A nonlinear antenna is a terrible beast indeed. It will mix every signal it receives with every other signal, creating a nasty mush of signals. On transmit it is not so bad, maybe generating harmonics and a wider signal than we'd like.

We've all heard stories of a poor antenna connection causing problems, or a nearby raingutter joint causing TV inteference. These are nonlinear antennas.

73,
Glenn AC7ZN

Mark, NM5K wrote:
"I refuse to admit it, if I can`t prove it."

A shield is extra work, weight, and cost but despite that, many are in use.

As electrons move along a conductor a magnetic field expands from some depth inside the conductor itself. The magnetic lines of force sweep outward from the conductor while inducing an emf in the conductor itself. The self induced emf opposes instantaneous change of current in the inductance of the conductor. This is the basis of Lenz`s law:
"In all cases of electromagnetic induction, induced electromotive force and resultant current are in such a direction as to oppose the effect producing them."

Skin effect prevents penetration of RF very deep into a good conductor. Skin effect makes RF coil shields impenetrable. Electric hields are shorted to ground by the conductive shield. Magnetic fields induce counter fields from the currents they induce on the surface of the shield.

A Faraday screen breaks the current path on the shield preventing the counter fields from being magneticly induced. Result is a shield that is penetrable by the magnetic field but impenetrable by the electric field. The electric field is still shorted to ground by its conductive path. Faraday screens are used because they work.

Best regards, Richard Harrison, KB5WZI

Perhaps "efficient" is the wrong word.

In my experience, it is quite difficult to send distinguishable Morse dots and dashes without a key (YMMV). Doing so by keying a mic or touching wires together thus becomes very slow - slower even than tap code. Also, it takes considerable effort to learn Morse and even more practice to copy all the less than perfect fists out there. Thus the number of operators and potential listeners who can copy such a 'bad fist' are few now and are rapidly vanishing now that Morse is strictly a hobby mode. OTOH, everybody who read my post now knows tap code - which is common in prisons, mines and other places because anybody can copy it with little or no practice.

I'm not suggesting that anybody eschew Morse if they enjoy it - just that they stick tap code into the back of their minds for emergencies.

Hi Richard, Yuri,

In regard to my last question that so stumped you two, there is absolutely nothing inherent in non-ferrous vs. ferrous materials that changes this one particular aspect of shielding. Both materials are conductive, and both are selected for their lowest conductivity (hence their lowest Ohmic loss). The only substantive difference is that a ferrous material offers the prospect of using a thinner covering for the same isolation. Above LF, this is hardly useful unless you are planning on using very thin foils. Art's selection of mylar films with conductive coatings is one such example that works with a conductive surface thickness in the 100s of microns.

The "shielded dipole" observes the one principle requirement of insuring that a break in continuity is maintained. Otherwise, the shorted turn snuffs the antenna for any design held within it. This prohibition in continuity is paramount to all designs and is driven by both magnetic as well as electric considerations, as in the RF field they are inextricably coupled.

To cut to the chase: there is no way to separate these fields and select one of them over the other. If you choose to run your arc welder within a loop's diameter of the antenna while also DXing; then it is the balance of the antenna design, not the shielding that will determine your success. Screw up the geometry of that gap, and you will hear as much hash as if the "shield" never existed.

For the standard single turn "shielded dipole," the arms of the dipole are the shield. There must be 10 million examples of this particular model on 1 million repeater installations world-wide. There are also tri-axial or twin-axial designs of the "shielded dipole" that wholly divorce themselves of the exterior shield. All such designs, to work effectively, exhibit a balanced configuration that is identical to the standard single turn. The balance is the only consideration at issue, and shielding is a means, but hardly a necessary ends to that achievement. As such, shielding is simply insurance and a brute force means to force balance through what in engineering terms is called

"swamping."

Hi Glenn,

Cecil is being deliberately obtuse to the matter of linearity. In the game of describing an antenna as a transmission line, the non-linearity is compellingly obvious.

If you start with standard twin line, its characteristic Z is dominated by geometry and a ratio of wire diameter to wire separation. Pull that twin line apart to construct a V or a dipole, and the geometry necessarily forces a non-linearity into the picture.

Reggie also has considerable difficulty with this concept too as he prefers to switch to earth as the main arbiter of transmission line dynamics. Both seem to abandon the generator's view of a 50 to 70 Ohm load to replace it with their 600 Ohm concepts so as to artificially impose their need to see a linear load.

These 600 Ohm concepts are achieved only if the operator strains to fail most spectacularly. Few debates are won this way, but arguments successfully persist for hundreds of postings. Even then, these concepts do not answer the initial non-linearity that inhabits the system. Both the 50 to 70 to 600 Ohm prognostications are artifacts of a measurement at the terminal of the non-linear device.

The proof lies along the line, and this returns us to the underlying concept and argument about the distribution of current along the length of the quarter wave dipole's arms. This is stated in terms of the Cosine function. However, as with a deliberate failure forcing an erroneous general solution, the Cosine distribution is only found in the extreme (or the fevered dream). A 1mm wire strung 36 meters in outer space is certainly thin by engineering conventions, but it doesn't qualify as the current distribution misses the mark of

Cosinality by 5 or 6% (the distribution of a poor fit demonstrates the non-linearity).

Given Cecil's penchant for abstracting considerable error to general proofs of his crystalline logic, this may not seem much. However, the precision above is not outside of achievement, and it does demonstrate with simplicity that linearity does not reside in the transmission-line-as-antenna. Pulling this antenna down to earth to allow the boys their investment in the 600 Ohm concepts does nothing to recover linearity - if anything, it worsens it (albeit, by very slim margins). Clearly, the dominant factor in the linearity of the dipole's characteristic Z is with its own wire. This has been long reported in the literature (Schelkunoff).

Further, to anticipate this does not demonstrate any spurious emissions - this is only due to your (not yours, Glenn, your in the sense of the general reader, and our boys with their loss of investment) inability to resolve them.

This class of non-linearity falls under the heading of "scattering" and in these most mundane of applications would barely present spurious products higher than 70dB below excitation, and only several parts-per-million from the center frequency (called Stokes shift). When Cecil comes to the table armed with slop on the order of ï¿½59% allowable error, such products are swamped in stupidity.

Good point. It is true that the original Morse code was merely clicks
and spaces on wired telegraph systems, similar to the tap method you
suggest. I see the advantage that by tapping slowly, anyone who knows
the scheme can copy. This is also true of Morse, of course.

Nobody said it was a perfectly ideal cosine curve. You seem to have
a strange definition of non-linearity as anything that differs from the
ideal. By that definition, everything is non-linear (including your
definition).
The definition of non-linearity being used here is "discontinuous".
Exactly where does the current in an antenna become discontinuous?

Heaven forbid the cosine curve exhibit the same accuracy as a resistor.
Would you also assert that a 52 ohm resistor that is marked 50 ohms is
exhibiting non-linearity?

Richard,

Wow. You spent a lot of time on this. Thanks.

Let's abandon antennas and postulate a twin-lead vacuum-dielectric 100 ohm transmission line that is ideal in the respects we consider important (except loss). There may be (resistive) loss, but no coupling to outside sources or objects, no hysteresis, no electromagnetic radiation. The characteristic impedance is exactly 100 ohms real over our frequency of interest. The velocity factor, for convenience, is 0.5.

We feed it on one end with a sinewave generator whose impedance is matched to the line. On the other end we terminate the line with a floating load of arbitrary impedance. The only requirement of the load is that it be perfectly linear and can be described completely as a real and imaginary impedance at any given frequency of interest.

Would you consider this system linear? We are not talking antennas now...nothing is radiating.

I'm not sure I'm going to go anywhere with this, and I'm not setting a trap. I'm just curious what conditions would have to be set before you would consider a transmission line system linear (you are welcome to add any conditions I might have forgotten). By the way, if you want to discuss any really subtle effects such a Stokes shifting, I define linearity as obeying the law of superposition within a reasonable dynamic range, say 140 dB, which is about 20 dB better than the input dynamic range of our best HF receivers.

I understand you are in an argumentative mood with others in the group, but I am taking no sides (I do happen to like Cecil's motorbike...) and will try to keep things civil. If I go anywhere with this, I hope to explain it clearly enough and with enough supporting material that there will be no arguments. I am not a guru so don't expect anyone to believe anything on my word alone.

So what say you Richard? Do we have linearity?

73,
Glenn AC7ZN

Hi Glenn,

Most of this time has long preceded these posts (by as many years as
Reggie has been posting here).

>Would you consider this system linear?

Yes.

>I'm not sure I'm going to go anywhere with this, and I'm not setting a
>trap. I'm just curious what conditions would have to be set before you
>would consider a transmission line system linear (you are welcome to
>add any conditions I might have forgotten).

I see no reason to constrain an open-ended topic; your definition is
fairly self referential after all:
I define X as a linear system;
Is X linear?

What correspondence that follows may upset the apple-cart, but aside
from the velocity factor gaff (which bears no relation, yet, on
linearity), I have no dispute.

What could upset the apple cart? Power.

Power has the capacity to distort systems and introduce
non-linearities even in your simple example. If I were to expand upon
what you call the subtle effects (they were in my earlier discussion);
this would give rise to back-scattering which could power limit the
line (in other words, it could never deliver more than a baseline
value). The onset of this condition is, again, nothing anyone here
has ever experienced, and to even approach this limit in the lines you
have constructed would tax most sources.

Such topics that may appear to be new here, have been exhibited in
fiber optic transmission lines for quite a while now.

Thanks a lot for this one, Richard.

And of course, Cecil has already ignored the important bits and state4d
that 6% is no big deal. Typical.

As I said earlier, the responses to Cecil are where the gold resides.

I had not heard of the Stokes shift, nor the scattering you mentioned.
I have some looking up and reading to do. Which, of course, Cecil does
not, since it's not a Xerox moment.

Yup, I hear that often, which is why I've had modest success with Jerry
Ziliak tapes. He sends at a character speed of 21 WPM, so each letter
almost becomes a single sound. Although that hasn't helped me much, thanks
for the thought.

Oh, yeah!!!! I am into packet and APRS, into building antennas for myself &
for the RACES stations and into teaching. Here in the West, we have
something called the Western Intertie Network System or "Win System"
http://www.winsystem.org/ which is loads of fun. It also has IRLP, so I've
chatted with guys all over the world with it.

I did HF PSK31 under the club license during FD a few years ago. Great fun.

I've became an ET in 1962 (USN) and liked it well enough to stick around for
21 years. I became an engineer in 1989 (thank you, GI Bill), so I know my
way around the 'trons. I've only been a ham since 1992.

Hi Tom,

It is pretty exotic, it only relates to radiation, reflection,
refraction, heat, and conduction, topics that are alien to discussion
here in more than TV Guide English it appears. Other difficult
concepts include linearity, coherence, mixing, and gain.

Stokes shift is the change in frequency due to the non-linear response
of a media to excitation. Typically the excitation is a photon
interacting with a phonon with radiation scattering following.
Injecting an electron (current) can achieve the same end. The effect
of power clamping in fiber optic transmission lines is due to SBS
(Stimulated Brillouin Scattering) threshold. I've been working with
this (Stokes and Anti-Stokes Shift) for some 20 years, and it fails
easy access through a copier.

The mention came only response to questions of linear response to what
at first glance would be a rather pedestrian transmission line
definition, but Glenn appears to have followed the clown instead of
pursuing his own question - he warned me it may have been pointless.

SBS and SRS (Stimulated Raman Scattering) would be suitable search
engine terms (esp. SBS threshold), but I warn you, they lead to
remarkably dense work where only one link in 20 will be accessible.

2710. Running wire close to HF transmit antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2006-05-19 06:06:08 UTC
From: Ben Jackson <ben@ben.com>
Message-ID: <slrne6qo2g.8u5.ben@saturn.home.ben.com>
Source record: 59252

Let's say I have a free-standing vertical HF antenna transmitting about 10wa, and I'd like to run wires to something at the tip. Say an anemometer, or a temperature sensor. What would be the best way to run the wire up the antenna? If the HF vertical is a pipe, is inside the best bet? If it's shielded wire next to a solid antenna, will that affect the radiation pattern of the antenna as a parasitic element? How much energy at the tip of the antenna will couple into the wire? If the wire is carrying low-speed digital data (eg for a 1-wire temperature sensor), how much isolation would it need (choke, AC couple, opto-isolate, etc) to avoid getting the HF into the digital signal?

Thanks for any insight!

However, in collaboration with a propagation prediction program, it gives you helpfull insights about influence of the pattern on the propagation and about the take-off angle most likely needed for point to point contacts on a given day, time and/or frequency. If you don't mind a little studying, you could try MultiNec, NecWin+ or 4nec2 with the VOACAP predication software. About EZnec I am not quite sure. To include terrain influence in all this, you could take a look at HFTA.

Arie.

Hello Dan, if you don't mind some additional studying, depending on
on-board RAM memory or if you are very patience, you could try 4nec2.
This will enable you to run up to 11000 segments without further costs.
To automatically create a wire grid (using the equal-area rule) or even
using surface-patches, use the geometry-builder.

Hi Ben

Keeping on mind that the data rate going to/from the sensor is very low compared to the RF I *think* they will co-operate. Some thoughts though;

- Opto systems have the problem that you need a power supply for the remote end. Using optical fibre is even a more elegant idea than wires but has a high-ish setup cost. You could of course use a IR LED/optotransistor config but as stated the power supply becomes an issue.

- You could argue that infrequent TX RF on the antenna even if it affects the sensor (data) can be ignored . This of course depends on what you are using the weather data for.

- If the weather data is a DC/AF level only you can allow RF onto the connection wire. Dont bother to try isolating it from the antenna at all. Dont even think of using shielded/coax. This way the effect on the antenna RF use will be small(er). You could get away with a choke/LPF or two at the antenna base, perhaps even with the use of coaxial stubs. (I'd start with a 1/4 wave open coaxial stub between each wire and antenna metalwork ground (ie where the antenna feed coax joins, then a other two further down)) Running the wire on the inside would of course be best for aesthetic and weather damage considerations.

- I'd say the effect of a base decoupled wire on the antenna would be neglible next to that of the aneometer or any box at the antenna tip. You would be capacitively loading the antenna at the "worst" place. (assuming a current node like at the tip of a 1/4 wave) ie it would need a retune.

Cheers Bob VK2YQA

Is this a multiband antenna? If so, I'd worry about the wire coupling different parts of the antenna to each other differently and requiring retuning at best, making it impossible to get a match at worst.

If it's a single band vertical, or at least just a single pipe without traps then inside is the best bet. What you probably want to do is put an RF choke both at the top and bottom.

Actually, I would suggest NOT putting the sensor at the top of a vertical, but rather put it a few feet from the top. The tip of the antenna is a high voltage point, and the top choke will be much more effective if it's at a lower voltage point where some current is flowing.

Run the wires up inside, use twisted pair, put a hole in the side of the antenna at a few feet from the top and attach an insulating rod sticking out sideways from that point. Put a good choke on the wires where they exit the antenna element both at the hole near the top and at the bottom of the element.

If it's a trapped vertical or something you'll have to worry about the extra coupling between antenna segments due to the wire.

If you're only running 10 watts (I think you said), I doubt you'll have to worry too much about arcing and so forth in the trapped situation, but it will probably detune the antenna quite a bit even if you run it inside.

Hi Richard,
Stokes' law and the Raman effect can be found in
physics texts dealing with quantum mechanics. Georg Joos, in
his book _Theoretical Physics_ deals with such things. The reading
is dense but the underlying concepts aren't too difficult. The
difficulty might lie in understanding how they apply to this

discussion.

Ben Jackson wrote:
"Let`s say I have a free-standing vertical HF antenna about 10 wa, and I`d like to run wires to something at the tip."

No problem.

All the stations I`ve worked in, medium wave and shortwave, had lighted towers. Some also used the towers to support other antennas and devices. Medium wave towers have sampling loops bolted to them for remote current and phase indications.

It`s dead simple. Conduit and coax are used to protect wires to devices and other antennas. Conduit and coax are firmly connected, top and bottom, at least, to the tower to shift most of the lightning to the lower-inductance tower.

At the bottom across the base insulator, coax is coiled to create a reactance at least 10x the feedpoint impedance of the tower. Similarly, each of the other wires running up the tower for illumination or other purposes is broken at the base for a tower-lighting choke (or Austin transformer) to isolate the RF and lightning. It works like a charm.

Hi Tom,

Certainly Joos would give some entry into the field, but finding work as accessible outside of a bookstore or library (in other words, through a search engine) makes for drinking out of a fire hose to quench a sip's worth of thirst.

Insofar as HOW this applies, I've spoken to that and Tom shows interest. That alone goes beyond the typical churning that passes for discussion. The point is that these underlying concepts are fairly simple as you imply and they are certainly not remote from the usual topics of consideration here. What they lack is specifics that relate to our common applications, and there too I've offered discussion. However, few seem inspired to travel those paths and that fault can hardly be laid at my doorstep.

Richard,

>>Who, in your estimation, does qualify to discuss it?

I would like to hear from someone who has actually measured the linearity of a simple antenna. I have not done this, so would only be one guy with an opinion. Plenty of us around.

By 'simple antenna' I mean an antenna such as a wire dipole without traps, baluns or other things that could degrade linearity. Since the linearity of antenna systems in general is in question, the simplest setup that answers the question would be best.

In the absence of measurement, can anyone comment on the modelling software? Does it assume and model a linear system? If so, do we know of any substantial nonlinear departures from the modelling software?

Anyone?

Richard Clark, KB7QHC wrote:
"Who. in your estimation, does qualify to discuss it?"

If it`s about antennas, I nominate Kraus. If it`s about mathematics, many marhematicians qualify.

In algebra, y = mx + b, (the point slope formula), is called linear because it is the graph of a straight line.

In the discussion of transmission lines and antennas, you must admit that a uniform transmission line enforces a unique characteristic impedance (a resistance) on energy traveling in either direction. A resistance is linear because Ohm`s law prevails. In free-space, everyone agrees the characteristic impedance is about 377 ohms (a resistance).

Kraus says on page 2 of his 1950 edition of "Antennas":
"Let the transmission line now be connected to a dipole antenna as in Fig.1-2. The dipole acts as an antenna because it launches a free-space wave. However, it may also be regarded as a section of transmission line (see Sec. 1-2). In addition, it exhibits many of the characteristics of a resonator, since energy reflected from the ends of the dipole gives rise to a standing wave on the antenna. Thus a single device, in this case the dipole, exhibits simutaneously properties characteristic of an antenna, transmission line, and a resonator.

Best regards, Richard Harrison, KB5WZI

Seems the easiest measurement of nonlinearity would be the
harmonics (if any) generated by the antenna that do not
appear in the source signal.

Hi Glenn,

Then you have a point in that regard. Bench work is rarely offered here and when it is, we are lucky if it is accompanied with the particulars of measurement so that it could be assessed or re-performed. It took very many years between cfa antenna claims, and legitimate field work by cfa proponents to show that their claims were unsupported.

>By 'simple antenna' I mean an antenna such as a wire dipole without

>setup that answers the question would be best.

Well, a BalUn is one of those elements that would be welcome so as to enforce the simplicity you demand, and so as to not disturb what is being measured. The BalUn (more properly, a choke) for this purpose would be for isolating the antenna from the transmission line.

>In the absence of measurement, can anyone comment on the modelling
>software? Does it assume and model a linear system? If so, do we know
>of any substantial nonlinear departures from the modelling software?

The modelers using NEC generally obtain results that conform to observable phenomenon. The modelers are supposed to be neutral observers. In other words, the non-linearity shown by the lack of congruence to the Cosine curve is not a presumption of non-linearity by the modeler; it is merely reporting an analysis. It may be noted that this analysis has been supported by a combination of bench work and theory.

All of this is the long way of saying non-linearity has been demonstrated, that is has been measured, and that it has been long explained. There are no surprises here.

Actually, for temperature, that might be the best idea yet. I could run the wires entirely inside, stop somewhere away from the top, and even disconnect the sensor with a PTT-triggered relay. The application is a beacon, so the transmit will be very intermittant anyway. I'd like to keep the entire antenna enclosed in PVC, with nothing hanging on the side, which is what got me thinking about INside.

Thanks for all the replies.

I use a "multi-band center fed doublet" for 80 through 10 meters. It is fed with 600 ohm open wire tuned feeders. Feeder length is just enough to get from the tuner to the antenna <G>, about 180 feet. The tuner/balun are bonded together and connected to electrical neutral.

No RF in the shack on 80 through 10. Well that's not really true. I'm sitting in the near field; but, I don't have RF hotspots on anything in the station at 1KW.

In order to measure something, you have to define what it is, first.
Cecil seems to think that in order for a simple dipole to be linear,
the current magnitude measured along its length has to be sinusoidal
in shape. Actually, though, I have it wrong. What he believes is that
since he can't detect any harmonics emanating from a sinusoidally
fed dipole, the current along its length must be a sinusoid. Actually,
it's supposed to be impossible to represent the current distribution
along a dipole using simple mathematical formulas because integral
equations have to be solved that are impervious to any solution
other than numerical approximation. That's why we need the various forms
of NEC. Cecil is wrong for the reason I've given in another post, and,
for reasons enumerated by Richard Clark. That won't stop the flow of
bellicose posts from him, though.

Hi Richard,
I didn't intend any criticism. People like Cecil, with
home-grown theories, don't ever seem to want things considered in
depth. That's understandable from a psychological standpoint, but
it isn't any help to the rest of us when some of the things the theory
ignores become significant. In the case of antennas, practically
everything is significant.

And a web search produced a couple very good links out of the first 20.
One was a great discussion of problems in long optical fibers, and
some relatively simple ways to work around some of them, or at least to
mitigate them.

Hi Tom,

In my early days in this game (late 80s), I sought to turn lemons into quantum-aide. That is, I sought erbium doped fiber optics to amplify nanowatt fluorescence signals with 10 to 50 ï¿½S decay times. Not one of those off-the-shelf commodities, however; so I had to amplify in the conventional way with an PMT.

For those interested, long haul communications fiber optics (transoceanic grade) met with the same requirements for amplifiers placed along the length to maintain S+N/N. Erbium doped fibers were projected as a solution. You could pulse UV into the fiber to charge it, and a IR data pulse would be amplified, continuously along its length. The IR data pulse would be boosted by the previous charge of energy. This is an example of forward Raman scattering and is called Raman Amplification (which at the time would have been about 30dB and 10% efficient).

Tom Donaly, KA6RUH wrote:
"Actually, it`s supposed to be impossible to represent the current distribution along a dipole using simple mathematical formulas because integral equations have to be solved that are impervious to any solution other than numerical approximation."

How many places do you attach to pi?

First, what is linearity? It is the absence of nonlinearity.

Millman and Seely wrote on page 525 of the 1951 edition of "Electronics" (one of my old textbooks):
"Because of this nonlinear characteristic of the dynamic curve over the operating range, the wave form of the output wave differs slightly from that of the grid-exciting-voltage waveshape. Distortion of this type is called "nonlinear" or "amplitude" distortion.."

All of the antennas I`ve worked with had no noticeable amplitude distortion. They caused no harmonics or mixing products.

On page 235 of Kraus` 1950 edition of "Antennas" he sets out to solve Hallen`s equation for current distribution. On page 239, Kraus writes:
"It is generally assumed that the current distribution of an infinitesimally thin antenna is sinusoidal, and that the phase is constant over a 1/2-wavelength interval, changing abruptly by 180-degrees between intervals."

You can take what Kraus says to the bank.

Best regards, Richard Harrison, KB5WZI

Subject: Spark gap - Marconi 2006

Hi Live-Wires,

With permission, I am posting the following regarding the Marconi 2006 event.

Dan W7OIL has informed the team leader that he is nearly ready with the passive receiver and adaptations for an INC.

So today, WI7B is happy to announce they have achieved spark in their 800 KHz rotary spark gap transmitter. They built it from a "Franken'd" Chevy V8 single point distributor and spark coil. With 7 VDC it generates a hefty 0.5 inch spark every 1/500 second (500 Hz rep rate).

I've attached photos of the setup and the spark gap, both un-energized and energized.

See the progress on the sparkgap here:

http://www.wireservices.com/n9zrt/Marconi-06/

Jim NY7T and W7OIL will be adding the LCR circuitry to the spark gap, then move it out the "ranch" to couple to a 375m quarter wave antenna.

The group has an STA from the FCC-OET to operate an 800 KHz spark gap transmitter. Callsign WC9XLG. They are legal.

It seems to me that we need to remember that radiation coming from the
feed line is cause by common current. If the feed line is balanced (no
common mode current) there will be no radiation from the feed line
regardless of the line's impedance or the feed point impedance.

That statement reflects your ability to comprehend what was written by
many, rather than what was written.

If you expected a specific length as implied by your question "What is
the correct way to determine the non-resonant feedline length of a
multiband doublet using 450 ohm open wire." then you have been
dissapointed.

The consistent answer (even if not always well expressed) was that
length is not particularly critical, though there may be some length /
frequency combinations (that are very dependent on your particular
implementation and equipment) that may challenge your ATU.

I go along with the advice to use a convenient length of feedline, and
if it is challenging to match up with the ATU, then lengthen the
feedline a little.

Your dissapointment is perhaps caused by your expectation of a
specific length.

Owen

Hi Richard,

This harkens back to your observation about how many places in Pi.

How much distortion has to exist before you hear it? As this directly relates to your quoted selection, are we to believe that distortion does not exist if you cannot perceive it?

This gives a great range of flexibility to the word linear through the careful selection for tone-deaf judges.

Back in the late 40s, Bell labs experimented with human subjects' ability to discern distortion. Turns out that they could take quite a bit (10 to 15%) before they could faithfully call it noticeable. So, by these stricter standards (Cecil would allow 59% before ringing the alarm) no distortion exists below 10%.

>All of the antennas I`ve worked with had no noticeable amplitude
>distortion. They caused no harmonics or mixing products.

No noticeable "amplitude" distortion? In a world of possible distortions, does linearity boil down to just one metric? Are you asking us to believe you anticipated any antenna would be non-linear and purposely tested them all? Nah, this is wholly unreasonable.

Richard, I frankly doubt you looked for spurs that would have been 70dB down in the worst of circumstances. More overwhelming would be corroded joints swamping that pursuit.

>On page 235 of Kraus` 1950 edition of "Antennas" he sets out to solve

>
>You can take what Kraus says to the bank.

So is Kraus bankrupt by contrary evidence that presumes he meant his quote to be taken strictly? Even Kraus hedges with "assumed" and he

does not otherwise force the conclusion, does he? Why indeed would he for such a trivial topic is the more astute observation.

This entire line of argument (distortion) is wholly specious. This violates most analysis by demanding that a wavelength sizeable element conform to lumped expectations. The non-linearity is found along the entire length of the element, not at a point. The characteristic Z varies by simple geometrical observation - it doesn't take quantum mechanics to arrive at this obvious conclusion. The ONLY linear quarterwave antenna is a biconical dipole - that has been established since the 40s. Even the Cosine distribution is blatant evidence of non-linearity (try listening to Mozart with an amp that has a cosine gain curve). An antenna has to be huge (wavelengths) and close (far less than a wavelength) to the earth before any linearity begins to arise - this too is historic.

Well, let me take a crack at it, if I may.

First-off: I don't think there's necessarily any single "right" length
of feedline, even for a single individual installation. There are
certainly a number of "wrong" lengths of feedline:

- The classic one - length is too short to reach the rig/transmatch

- Too long - feedline drapes on the ground, is looped around near
metallic objects, etc. - and there are excessive losses or shock
hazards

- End-of-feedline impedance on one or more bands is outside the range
which can be matched properly.

The first two sets of conditions are fairly easy to pin down. :-)

The third is, I think, the place where the interesting variables come
in. Transmatches aren't all equal, by any means, in the ranges of
impedances that they can match (and the matchable impedances don't
necessarily form a nice SWR-value circle on the Smith chart!), or the
losses in the tuner, or the amount of power that the tuner can handle
before it starts to suffer from arcing or balun overheating/saturation.

It's likely that in any given installation, there will be multiple
lengths of feedline which will allow a match on a particular set of
bands. The matches will probably vary in efficiency and Q. Which one
will be "best" is, to some extent, a value judgement by the installer
and will depend on how the station is going to be operated. For
example, if you spend most of your time operating on one or two bands,
you might choose a feedline length which allows efficient and fairly
low-Q transmatch settings, so that you don't have to adjust the match
as often (or as critically) when QSY'ing within a band.

Now... how to evaluate the possibilities. Here's one approach which might be worth trying - it's a bunch of work but should let you end up with some useful data.

[1] Grab a whole bunch of Smith chart blanks (or get some good Smith chart software, or some other software which lets you handle impedance transformations conveniently).

[2] Figure out the minimum and maximum lengths of feedline which would be physically acceptable in your installation... from the shortest which will reach the rig, to the longest which can conveniently be zig-zagged back and forth between feedpoint and rig. Convert these lengths to electrical length (i.e. divide by the feedline's velocity factor, if it's much less than 1.0).

[3] For each band, convert the minimum feedline length into wavelengths, modulo 1/2 wavelength (180 degrees). Also, calculate the difference between minimum and maximum feedline lengths in wavelengths. If it's more than 180 degrees, just call it 180.

[4] Determine the range of impedances that your transmatch can handle, on each band that you're interested in working. You _may_ be able to use whatever blanket marketing/spec statement the tuner manufacturer provides (e.g. matches any SWR < 10:1, "all impedances from 25 to 1000 ohms", etc.) but it wouldn't hurt to run some tests yourself. You may wish to rule out some impedances even if they're theoretically matchable - e.g. a T-match tuner can often produce a "match" to a near-short-circuit, but the losses in the tuner are so high that it's not worth the bother.

[5] For each band, plot the range of matchable impedances on a Smith chart which is normalized to the nominal impedance of your balanced feedline. Use one Smith chart per band to avoid confusion.

[6] Choose the length of your doublet, based on space available and/or desired pattern on one or more bands and/or lore and/or any other criteria you desire.

[7] For each band, use appropriate tables to determine the feedpoint impedance of the doublet on the band in question. You may wish to calculate several values when the band is fairly wide (e.g. 80 meters).

[8] Plot the doublet's feedpoint impedance for each band on that band's Smith chart.

[9] Using a compass centered at the Smith chart's origin, rotate the feedpoint impedance "towards generator" by the number of degrees corresponding to the shortest-possible feedline length, as calculated in step 3. Plot this point.

[10] Use the compass (centered at the origin) to draw an arc from this point, in the "towards generator" direction, for the number of

degrees corresponding to the difference between minimum and maximum feedline lengths.

What this should leave you with (we hope) is a chart for each band, which shows where the antenna's feedpoint impedance, transformed by the feedline, falls inside the range of impedances that the transmatch can handle. If the impedance arc comes near the centroid of one of the "We can match this" circle/blob, then the closest-to-centroid point on the arc would correspond to a feedline length which might be a very good one for that band.

If the arc doesn't enter a band's matchable circle/blob at all, or just barely enters it, then you may wish to go back to Step 6, pick a different doublet length, and try again.

Now, what you can do is take a piece of paper and draw a straight line. Put the minimum feedline length at one end and the maximum at the other.

For each band, look at the impedance arc, record the sections at which it's outside of the matchable-impedances blob (measure the number of electrical degrees of rotation from the load), and figure out the feedline lengths that these unmatchable sections correspond do. Use a colored marker to denote these lengths on the straight "minimum to maximum feedline" graph. Borrow color markers or crayons from your kids so that you have one color per band :-)

Once you've finished doing this for all of the bands you're interested in, take a look at the straightline graph of feedline length. If you're unlucky, *every* point on that graph will be colored as "not matchable" on one or more of the bands that you care about. If so, you can go back to Step 6 and try a different doublet length, or you can resign yourself to having to switch between two different lengths of feedline when QSYing.

If you're not unlucky, there will be at least one range of feedline lengths which can be matched on all bands. If so, I'd suggest choosing a length which causes the impedance arcs you plotted to fall near the centroids of the matchable-impedance areas, on the bands that you use most heavily.

The above is very much a manual procedure, requiring at least an hour of calculating and plotting and cussing. There are almost certainly some software tools which can be used to automate and simplify this process.

I keep going back to my very old ARRL antenna handbood which shows a
chart of favorable lengths of feedline. Is it wrong?

I also would like to point out W8JI website and the lengths of feedline
that he recommends, which seems to be consistent with my ARRL handbook,
1960 edition, for this type antenna:

http://www.w8ji.com/short_dipoles_and_problems.htm

Arrow down.

My 2000 ARRL Handbook describes a 135' multiband dipole antenna but
does not make any recommendations on preferred feedline lengths.

Perhaps they have changed their mind since your edition was published.

Given sufficiently good transmission line, lengths to avoid are only
lengths to avoid because they present a load that the tuner cannot
efficiently transform, or the voltage exceeds the capability of the
tuner.

Highest voltages usually occur at frequencies much lower than the
first parallel resonance... so avoiding resonance doesn't address the
most significant region of high voltage.

He does more than recommend a feedline length in isolation of other
parameters.

Tom's article is relevant and interesting.

You will see that he links to articles by Cebik and myself on the
G5RV.

Also relevant to the multiband dipole application is the analysis in
my article at http://www.vk1od.net/LOLL/index.htm and its reference
documents.

To get off the 1960 tram, factors that are relevant are:
- they probably did not foresee the WARC bands and design to include
those bands;
- the regions where efficient transformation is a problem are usually
very narrow, but quite dependent on the exact implementation
(including proximity of other conducting objects, ground / weather
conditions), and locating them outside amateur bands may require
in-situ tuning.

Richard,

Maybe someone can help us here. Linearity is well-defined in electronics by the law of superposition, and is characterized by well-known measurements such as harmonic generation, compression point, and third-order intercept point. I'm assuming antennas must follow the same law of superposition while transmitting and receiving to be linear.

It is not clear to me that a nonlinear or even unpredictable current distribution along a wire antenna produces signals that violate the law of superposition. Under a strange current distribution the antenna radiation pattern will certainly distort, but how does that violate the law of superposition? That is, how can a strong received signal influence a weak one on an antenna with nonlinear current distribution?

Maybe, like so many other threads in this group, we are discussing orthogonal concepts.

I believe you're correct.

As I see it, in the *general* sense, linearity refers to a
relationship between two variables, where the relationship is one of

OUT = IN * F + C

where F and C are constants (plus a dimensional factor in many cases).
In other words, it's a straight-line relationship (hence, the name)
between two variables of the same or different dimension.

The sort of "linearity" that people usually refer to in electronics,
involves voltages and currents (vs. one another). A theoretically
perfect resistor, capacitor, or inductor is linear, because (e.g.) the
peak current through it has a strictly linear relationship to the peak
voltage across it.

A semiconductor junction is described as nonlinear, because the
current through it is not related to the voltage across it in a
strictly linear relationship.

The sort of "linearity" which Cecil seems to be referring to (if I
understand what he's written correctly) involves a completely
different sort of relationship. It's not current-vs-voltage, or
voltage-vs-current - it's current-vs-distance.

If I recall correctly, an infinitesimally-short "monopole" has a
current-vs-distance relationship which is close to linear. A
half-wave monopole does not.

Nonlinearities of this sort would have entirely different effects on
an antenna system than nonlinearities of the voltage-vs-current sort.

They're two different beasts entirely.

And what do these numbers prove? Not a bleeping thing.

I don't think any correlation exists between them and current behavior on HF, which I assume, possibly incorrectly, that you are refering to.

The biggest idiots on 20m, for instance, are on 14275, both sides are guilty, and I am quite sure that they all got their tickets with CW required. And the problem stations on 75 are quite the same. Which also proves nothing either way.

The cleanest, most public oriented operators are on 2m and 70cm, and many, or maybe most, of them did not have to pass any CW exam. They participate in Skywarn, emergency drills, and tons of other things. By and large they are good citizens. The bad actors I have seen come from all parts of the amateur community, with probably the worst from the longest licensed, who seem to feel they have some sort of rights from being around a long time. My personal sample could be wrong, but I don't think so; I've been around a while, too.

The older generation always predicts that the current one is going to cause the end of the world. Or whatever imagined disaster they are concerned about. And they are always wrong.

I would agree, Richard, but at HF frequencies the current path
around the shield isn't really broken by the gap. Due to the skin
effect, the RF current flowing on the inside of the loop shield is free
to flow around the edge of the shield conductor and onto the outside
of the shield at the gap. At very low frequencies, where the skin
depth is large, this wouldn't necessarily be true, but at HF as long
as there are a few skin depths between the outside and the inside
surface of the conductor, then the inside surface of the shield and
the outside surface of the shield can be treated as independent
conductors.

It certainly is interesting how many supposedly knowledgeable people
can't tell the difference between length and time. Millman and Seely
were writing about cycles per _second_. Kraus was talking about
distribution over _length_. Moreover, read Richard Clark's post
on this subject. Brother!

You are being fooled by an illusion. Any deviation from
single frequency sinusoidal signals would generate harmonics
which we know doesn't happen. Your "non-linearity" is not
really there. For instance, a decrease in VF may compress
the waveform but that is not non-linearity.

The non-existence of harmonics is prima facie evidence
that only single frequency sinusoids exist. A properly
functioning antenna system is linear. Any perceived
non-linearity is an illusion.

Yes it would. It would be proof that the current distribution
along the length of the dipole is sinusoidal no matter what
your illusionary perceptions are telling you.

For standing wave antennas, if the source is a pure single
frequency sine wave and if no harmonics are generated
by the antenna system:

1. The forward wave is sinusoidal.

2. The reflected wave is sinusoidal and coherent with the
forward wave.

3. Their superposition results in a sinusoidal standing wave
with the same angular velocity.

Any non-linearity would introduce harmonics.

All of the theories I am quoting were developed long before I was
born. Almost every technical explanation starts out with simple
concepts and proceeds to more complex concepts. For the sake of
teaching and understanding simple concepts, the secondary variables
are often ignored for the time being. Thus, every textbook on
transmission lines starts off with an explanation of lossless lines
with perfectly resistive characteristic impedances even though such
lines don't exist in reality.

Assuming thin constant diameter wires with a constant Z0 and VF.

If the diameter of the wire changes, or Z0 changes, or VF changes,
the 'K' term in the cos(KX) expression changes. A change in a
constant does NOT produce non-linearity in a linear system. Just
because a wave slows down in a medium with a low VF doesn't mean
that the system has gone non-linear.

Of course, Kraus is talking about the cos(KX) term
where 'X' is _length_ and 'K' is the constant that
converts that _length_ into degrees. Given 'K',
length and degrees are perfectly correlated.

Thanks for all the links which I am reading. My dipole is about 126 feet long which should be about right for 3.7 Mhz. I mostly use it on 75 M. The new feedline I have installed is a bit shorter than what I was using, I think it's now around 47 feet, the old stuff was 50 plus feet. I notice my Johnson matchbox now finds it somewhat difficult to tune up this antenna on 40 M so I may have to add on a few feet. A couple of years ago I had two loading coils on each leg of the tuner output and the whole thing was a perfect match on 75 and 40, all I had to do was change the bandswitch on the matchbox, nothing else.

I guess I'll just not worry about length of feedline only to make it tune nicely and fit the physical space from the antenna.

Did you take a look at the information on my web page at:

http://www.qsl.net/w5dxp/notuner.htm

It tells you everything you need to know about that antenna
including why 47 feet is not the best feedline length on 40m.
In particular, the chart at:

http://www.qsl.net/w5dxp/pnts130.gif

shows the best lengths for 40m to be 30 feet or 92 feet.
A good compromise single length for all-HF-band operation
is 100 feet.

The purpose of most antennas is to radiate electromagnetic waves.
That means there is loss. It also means that the current envelope is
affected. That's one of the reasons we use EZNEC. I suppose, Cecil,
that if you keep repeating the same old tired line, over and over
again, you might find someone who will agree with you. Certainly,
no antenna measurement would.

Are you going to run QRP? I made mind out of 1/2 copper tubing and
made loop from coax at the top the tuning capacitor I used was from
ebay the spacing between the tuner is 1/4 inch my tuner is 4" wide
6"long and about 3 1/2 high first contact 22" off ground was Detroit
Michigan I'm in Dunedin Florida second contact was Canada for about
a half hour. with a small tunable cap you will have arking I am
running 100 watts. Jim De W8OLD

The current envelope is affected but remains a linear
system function since it is the result of superposition
which itself is a linear system function.

> I suppose, Cecil,
> that if you keep repeating the same old tired line, over and over
> again, you might find someone who will agree with you. Certainly,
> no antenna measurement would.

The current envelope is a linear system function. I am
repeating the rules and laws of mathematics. Sounds
like you need to review the definition of linear systems.
You can do that at:

http://www.cns.nyu.edu/~david/linear-systems/linear-systems.html

In particular, quoting: "Systems that satisfy both homogeneity
and additivity are considered to be linear systems. These two rules,
taken together, are often referred to as the principle of superposition."

In general, antennas are linear systems that satisfy the principle
of superposition. If they were non-linear, they would not satisfy
the principle of superposition. Two linear system functions, like
forward waves and reflected waves, cannot superpose to a non-linear
function. Therefore, standing waves are linear, not non-linear,
functions. To argue otherwise exhibits a certain degree of ignorance.

Until the obvious mathematical misconception is corrected, no
rational discussion is possible. To the best of my knowledge,
Maxwell's equations are also linear system functions so claims
of non-linearity also contradict Maxwell's equations.

Yes I did Cecil. I went out and remeasured and found that I have about
67 total feet of feed line now. I may shorten that up again. I'll
re-check the links you provided, thanks.

BTW Cecil, I could never get 100 feet of open wire in my back yard
unless I coil it up or string it all over the place and that would not
be good. Isn't there a shorter length that would work for 75 & 40?

> Or does it?

I dug out my linear network theory book and would like
to present a few quotes and comments:

"The real world is inherently non-linear."

Lightning hitting an antenna can cause arcing and melted
wires.

"Although nature is non-linear, linear approximations over
defined ranges of validity are valid representations of
non-linear phenomena."

Amateur radio antennas are usually confined to that limited
linear range.

"The necessary and sufficient conditions for a linear system
are: (1) validity of the principle of superposition;
(2) preservation of scale factor.

Does doubling the power input to the antenna ~double the
radiated power? Does it ~double the non-radiated losses?

"Fortunately for the engineer, however, linear systems are
frequently excellent approximations to reality and have a
wide range of validity in the real world."

Maxwell's equations in particular. Textbook equations for
traveling waves and standing waves assume linearity.

(30+92)/2 = 61 feet, worst case for feeding that dipole
on 40m. For all-HF-band operation, I would highly
recommend a feedline length of 100 feet. You can use
a 60 foot run of small non-conductive rope with the
ladder-line spiraled around it and tie-wrapped to it
to obtain the better case 100 feet.

As you can see from: http://www.qsl.net/w5dxp/pnts130.gif
the 3.8 MHz feedline needs to be about 110 feet. Worst case
for 3.8 MHz would be about 55 feet. Why can't you use a non-
conductive messenger rope and spiral the 100 feet of tie
wrapped ladder-line along its 60 ft. length? That has worked
well for me. I predict that your tuner will have no problem
tuning 100 ft. of feedline at least on the lower bands. Since
your antenna is 3 feet shorter than mine, it may exhibit
different characteristics on the higher bands.

Hi Owen,

There is one way to obtain a simple answer, you make the transmission line an odd 8th wave long which will offer reasonable tuning. This insight comes courtesy of Walt Maxwell's techniques offered for measuring steep loads found in his classic "Reflections."

You can still pretend a dipole is a "linear system," as you call it, and still understand that the current envelope is not a simple sine function. The Achilles heel of all your reflection mechanics ideas is the assumption that everything is lossless. (Not to mention the fact that it's supposed to exist in outer space.) You and Reg like to think of a dipole as a transmission line, and Reg can even tell you its characteristic impedance (average). What neither he nor you ever mention is the alpha part of the propagation constant. That's the important part, though, since it signifies radiation, the very thing the antenna was designed to do.

By the way, why are you quoting from a network theory book when not too long ago you were ranting and raving about the invalidity of the lumped constant model?

Well I'll give it some thought. All I need is to find room somehow for
33 more feet of ladder. Maybe I will try it jury rigged first to see
how it tunes, but not today, it rains. Doesn't the matchbox do the
electrical tuning of the feedline instead of using fixed lengths as you
are doing? As you said the length I have now does not tune very well on
40, I can get it to work but it's like opening a safe.

I just dug out my Drake MN-2700 user manual and it says to use 135 foot
long horizontal fed in the middle with 67 feet of ladder. Weird, this
stuff is worse than making a pizza.

There's no test for one important ham skill: typing. I didn't appreciate how important it is until I learned that one of my pro-Morse buddies does all of his sending with a computer. (He can send with a key but doesn't know where his is.) He says he copies with the computer, too, although he can follow along with the audio.

I asked around and found this practice is far from rare; I'm not sure "common" is the right word, though.

We also might want to test for basic language skills, including punctuation. While it's not always true, the disagreeable transmissions (and NG posts) often make the speakers/writers sound pretty ignorant.

Diverting to a "simple" sine function in the same spirit as
diverting to a "small" loading coil?

If you were always talking about a perfect sine wave, you should
have said so long before now and nobody would have disagreed with
you.

> The Achilles heel of all your reflection
> mechanics ideas is the assumption that everything is lossless.

That's NOT the assumption. The assumption is that lossless systems
are easiest to understand so let's understand them first before
we move on to something more complex. You guys have proven that
you don't even understand the simple lossless condition.

> (Not to mention the fact that it's supposed to exist in outer
> space.) You and Reg like to think of a dipole as a transmission line,

> signifies radiation, the very thing the antenna was designed to do.

Only about 1 dB of the steady-state energy stored in a 1/2WL
dipole is radiated so radiation is not the largest effect. The
radiation from an antenna can be simulated by using resistance
wire to simulate a 1 dB loss in a transmission line. The reason
that I have rarely mentioned such is that you guys don't understand
enough of the basics to proceed to those more complex examples.

> By the way, why are you quoting from a network theory book when not
> too long ago you were ranting and raving about the invalidity of the
> lumped constant model?

The lumped constant model is valid under certain conditions. What I
object to is its use under known invalid conditions. The lumped constant
model and distributed network model are both *linear systems*.

Richard,

The original question was regarding a multiband double of unspecified
length.

Aren't there lengths of the dipole that in concert with an eight wave
feedline would challenge the ATU?

Have you made assumptions about the doublet length in making this
recommendation?

Owen

If it's a Johnson Matchbox, it has a limited tuning range.
But for dipoles 1/2WL at the lowest frequency of operation,
feeding in the rough vicinity of the current maximum point
will work. For 80m and 40m, you might get by with 80 feet
of feedline.

> I just dug out my Drake MN-2700 user manual and it says to use 135 foot

If that is for 80m or 40m, the Drake must like very high
impedances.

Drakes idea is probably a versatile antenna similar to the one on page 22.11 of the 2006 ARRL Handbook.

At 80 meters it is about 1/2-wavelength fed with about 1/4-wavelength of feedline. A grounded radio presents a high impedance to comon-mode travel where the line meets the antenna at the resonant frequency of the antenna. Your radio should not bite you on 80 meters and a versatile tuner should make the antenna useable through 10 meters. The pattern goes through a lot of change in that range of frequencies. This is predicted by a modeling program and some of the transition is shown in the handbook.

Best regards, Richard Harrison, KB5WZI

First, I couldn't find you an HF/VHF diplexer, but you can build one.
http://home.datacomm.ch/hb9abx/diplhf6m-vuhf.html

Second, do you have to have both radios functional simultaneously or are you willing to switch one antenna between to radios? If you're hamming you probably don't want the BCST radio playing in the background.

Here's my story:
Years ago, I developed an open shield in my van's BCST antenna and I didn't want to tear apart the dashboard to replace the antenna, so I put a Motorola-to-BNC adapter into the back of the car radio. From there I dropped a short length of coax down, ran it under the floormat to a point behind the seat and connected it to my MFJ magmount's coax. (If I'm hamming, I disconnect the BCST radio and use the magmount as MFJ intended. I never bothered to install a switch.)

My $15.95 (last time I bought one) MFJ Dual Band magmount works perfectly as a substitute for the car's BCST antenna -- AM & FM just fine. BONUS: On long inter-city trips, I swap out the stock whip for a longer, straight whip and the BCST reception is just wonderful.

I'll give the 100 ft a go and let you know.

When you say wind the ladder line around a tag rope, I assume you mean
to use ties around one wire of the ladder and make the loop maybe a foot
in diameter or maybe 6 inches? Sort of a helix affair. Would that
cause a problem with the ladder being so close to the turns? I've read
where I should keep the ladder from sharp angles and away from metal
objects so as not to unbalance the line and destroy the cancel
properties of ladder line.

The more I read about this the more it looks like black magic.

Probability certainly suggests so. Russian roulette's popularity is based, in part, with the notion "I'm feeling luckier than you." We can both agree that perhaps the same mind-set is at work dreaming in Technicolor and surround-sound for this doublet.

>Have you made assumptions about the doublet length in making this
>recommendation?

Hi Owen,

That was the point of my (Walt's) choice of an odd 8th wave length transmission line, at least for a fire breather load, it pulls it into a relatively placid range for matching (measuring).

If the original poster needs a simple rule, the odd 8th wave is good as any. However, if this is in an effort to cover every band, series/parallel resistors will do the job every time.

47', now 67'... slowly more information emerges, even if changing.

The following is a one band (40m) perspective of your multiband
antenna.

If you have a 126' dipole (as you said), it has a feedpoint impedance
that is quite high around 7MHz because it is close to a full wave
dipole which has a feedpoint impedance around 4200+j0 (depending on
height, ground etc). A 126' dipole 15m above average ground is
probably around 3600+j1400 at 7.2MHz.

If you were using 67' of Wireman 551, you would expect the load seen
by the tuner to be around 660-j1400 ohms (assuming an effective 1:1
balun)... which is not extreme, but it is fairly high and might

challenge some ATUs. Lengthening the feedline will bring the load impedance down fairly quickly, just another 10' (ie 77' overall) gives 90-j400. Shortening the feedline a little from 67' will make it worse, 62.5' will give you the maximum load impedance of 3500+ ohms.

Standing back and taking a system view, it is questionable whether making the dipole resonant or very close to resonance at 3.7MHz as you have done, makes harmonic operation easier. It certainly presents the worst case feedline VSWR on 7MHz, the highest feedline voltage (>2500V peak at 1kW), though the transmission line loss for 90' of 551 is only 0.6dB in the above scenario.

Owen

PS: I know conventional wisdom is to make a multiband dipole half wavelength at the lowest operating frequency, and the ARRL shows such an antenna with 130' dipole length.

It turns out that if a dipole with practical length of open wire feeder to an ATU at the tx is less than about 35% of a wavelength, system losses increase dramatically with reduced length, so the dipole should not be less than about 35% of wavelength at the lowest frequency. You can see the effect in Fig 2 of my article at http://www.vk1od.net/LOLL/index.htm . In that case, the system losses with a 66' dipole are acceptable down to about 5.5MHz, for 3.5MHz the dipole needs to be greater than 5.5/3.5*66' or 103'.

To best describe what broken means, a picture helps. There is a picture on page 13.18 of the 2006 ARRL Handbook. Fig 13.26 has a legend which says:
"To prevent shielding of the loop from magnetic fields, leave the shield unconnected at one end."

I think the handbook has it right.

Hi Group,

I looking at convering a TV UHF antenna to 2.4 GHz, the antenna has a yagi part with elements spaced every 3 inches and the elements are the same lenght of about 3 inches.

I think the 3 inch element lenght are a little long, and the elements need to be cut so that one of them is the reflector and one as a driven elements and the others would be come directors. There are about 10 elements on this boom.

The element spacing, 3 inches most likely will do OK ? comments?

A look in the handbook for 2.4 GHz antenna, either they don't include them or I missed them. I have several old handbooks and ARRL antenna books.

So, would as anyone who has some of the basic dimensions to pass that along.

Also concerned that the frequency will require a SMA or Type-N and matching, I don't have a means to check the SWR.

Well, I've not tried THAT, specifically, but my MFJ939B will load a 50foot
piece of what looks like 200 or 150 ohm twinlead with half of one side
stripped away just fine, if I connect up the internal balun. And I mean
LOAD it--on any frequency from 1.8 to 30mhz.

I've also loaded small loops with it well off their resonant points and use
it all the time to lead hamstick whips well off their resonant points.

I don't think you'd have any real trouble as long as the 600 ohm line ran
straight away from the antenna, at least in the near field.

I am a bit behind on ARRL Handbooks, Richard, but from
what you describe, this is the same figure that appears in my
1992 edition (chapter 38, figure 2). In any case, what is
shown in the figure agrees with my understanding of "broken",
although admittedly when I made my previous post, I was
thinking of the case where the shield is broken on the side of
the loop opposite the feedpoint. For the purposes of this
discussion, however, it doesn't matter whether the break is
at the top (opposite the feed) or at the bottom (adjacent
to the feed). In either case, current induced on the inside
of the shield by current flowing on the center conductor loop
has a continuous back to ground via the outside surface of the
shield. IOW, the gap doesn't suppress the eddy current, rather
it forces it to flow on the outside surface of the shield, thereby
causing the loop to radiate.

>
> I think the handbook has it right.
>

Yes, I agree it does. If you connect the shield at both ends, the
loop can't radiate because the eddy current caused by current
flowing on the inner conductor loop will confined to the inside of
the shield. Likewise, eddy currents induced on the outside of the
shield by EM waves passing the antenna will be confined to the
outside of the shield if there is no gap (reciprocity holds - the
antenna won't receive with no gap).

Absolutely nothing, neither electic nor magnetic, couplesthrough the
wall of a conductor more than several skin depths thick. This isn't
anything that can be debated, it is simply how it works. It is very
easy to demonstrate, it takes only a few minutes and a minimum of test
equipment.

It is something very basic in physics and underlies how coaxial cables
and things with shields of all types work.

The gap is the feedpoint no matter where the gap is placed. The
radiation and coupling of any time-varying field, magnetic or electric,
occurs on a frequency where the shield is more than a few skin depths
thick comes by the gap.

This is such a very basic thing it is important everyone understand it.

> > I think the handbook has it right.
> >
>
> Yes, I agree it does. If you connect the shield at both ends, the

Absolutely. When the gap is closed there is no potential difference
across the gap the outside of the shield is not connected to the inside
of the shield via the potential developed across the gap. The outer
wall is not coupled to the inner wall, the feedpoint is shorted.

When the gap is opened, the outside of the shield IS the antenna. Not the inside or anything inside the inside.

> Likewise, eddy currents induced on the outside of the
> shield by EM waves passing the antenna will be confined to the
> outside of the shield if there is no gap (reciprocity holds - the
> antenna won't receive with no gap).

Again true. This is a very basic thing we must understand if we are to understand how shields, walls, or conductors of any kind or form work with HF currents, voltages, or fields of any type.

There isn't any way to change this effect.

73 Tom

I don't think we disagree on that point, Tom. Perhaps I should
have chosen my words more carefully. I didn't mean to imply
that gap somehow forces the current on the inside of the shield
to pass through shield. When I said that the gap forces the current
to flow on the outside surface of the shield, I meant that in the
sense that the eddy current flows on the inside of the shield until
it reaches the break in the shield at which point the current flow
wraps around the edge of the shield and onto the outside surface
(thereby reversing direction relative to the direction of the eddy
current on the inside of the shield). The skin effect in effect
separates the shield into two distinct conductors, the inner surface
being one conductor and the outer surface of the shield being the
other. The gap is the circuit node where these two independent
conductors are connected. The eddy current flows out of one
conductor (the inner surface of the shield) and into the other
conductor (the outer surface of the shield).

I have a 130 foot dipole, about 25' high in the middle, 20' at the
ends, fed with 47' of the Wireman's ladderline, going directly to the
4-1 balun of an old mfj989c tuner. From everything I've read in this
thread, it shouldn't tune worth a darn on 40 meters, but I can get a
1-1 swr match on 40, as well as every other band. I guess all you can
do is put it up and see if it works :-)

One of these days I might try Cecil's idea, a 100 foot feed of
ladderline, but I'd have to string about 50' of that back and forth to
make it work.

You are forming 100 ft. of ladder-line into a 50 ft. long helix.
The spacing on the turns will not be a problem as it will be
a very loosely wound helix. Tie a knot in the messenger string
every 10 inches. Anchor one point of the ladder-line to a knot
in the messenger string using black tie-wraps. Take 20 inches of
ladder-line and anchor it at the next knot down from the first knot.
That will give you one turn of the helix. Repeat until you have
a 100 foot feedline. If you didn't want to use tie-wraps, you
could tie the 10 inch spaced knots through the ladder-line every
20 inches of ladder-line.

When I was using an ICOM-706, I didn't use a tuner. Now
that I have an ICOM-756PRO, I choose a feedline length
that resonates the antenna system in the center of a
band and then use the autotuner for excursions toward
band edges.

Making the feedline a fixed length of 100 ft. and then
using a tuner is somewhat similar to what I am doing now.

Agrees pretty closely with Walter Maxwell's 3/8 wavelength
minimum dipole advice.

Agrees pretty closely with the length of a G5RV.

Do 60 Hz magnetic fields penetrate RF coax since
the conductor is not more than several skin depths
thick?

That "1-1 swr" is on the coax between the tuner and the
transmitter. The SWR on the ladder-line is probably around 12:1.

I'd suggest it isnt worth attempting. The frequency change is more than
3:1 from the original TV use.

There are a lot of simple 2.4GHz designs out there that are worth
looking at.

> impedances.

I just tacked on additional ladder line for a total of 91 feet, it's
draped all over the place. The matchbox tunes more difficult on 75 M
but tuned right up on 40. The matchbox controls are skewed quite a ways
off the center point. tuning control is at 26 and match is about 15 so
it does not seem to like this length any better. I could tack on
another 15 feet but then I'd have to lay it on the ground which is not
good. I could shorten up the original 67 feet to perhaps 50 plus but
that would make it worse?

The Drake MN2700 uses a 4 to 1 balun for matching ladder line. I use my
Johnson KW matchbox for the ladder line.

If I were to use W7FG's 600-ohm line, would 100' still be a good
length?

Hi KJ4UO

I assume that you dont have alot of experience with designing and building Yagi antennas. If you have no test equipment for testing at 2.4 GHz, you will undoubtedly be at the mercy of luck, good or bad.
If your goal is to have a WiFi yagi, there are affordable Yagi antennas available for less than $100.00.
If your goal is to build your own WiFi antenna, I'd suggest you consider using other than a Yagi. You have probably searched the web and know about the cantenna. And, a small satellite TV dish is easy to convert to 2.4 GHz.

Jerry

I just dug out my Practical Wire Antennas book by John Heys, G3BDQ,
RSGB 1989, P. 16 & 17 "centre-fed antennas using tuned feedlines", and
it collaborates the information in my old ARRL 1960 handbook which says
to calculate one half of the horizontal wire plus the feedline length
and that total number should not equal certain critical lengths one of
which is 160 feet on 3.6 Mhz, there are more. I hate to beat this to
death, but frankly I don't think any of us has a clear understanding of
this antenna.

Dalej.

When I read that in the clarity of a new day, I can see that is not
correct as written, I should have said:

It certainly presents the worst case feedpoint impedance at 7MHz, the
highest feedpoint voltage (>2500V peak at 1kW), though the
transmission line loss for 90' of 551 is only 0.6dB in the above
scenario. (A shorter dipole may result in higher voltage along the
feedline, and higher feedline loss, depending on the lengths of each
of dipole and feedline.)

Tom, W8JI wrote:
"Absolutely nothing, neither electric nor magnetic, couples through the wall of a conductor several skin depths thick."

That`s wrong for a "Faraday screen".

Terman is right. At the bottom of page 38 of his 1955 edition he writes: "It is possible to shield electrostatic flux without simultaneously affecting the magnetic field by surrounding the space to be shielded with a conducting cage that is made in such a way as to provide no low-resistance path for the flow of eddy currents, while at the same time offering a metallic terminal upon which electrostatic flux lines can terminate."

An example exists in the AM broadcast stations I`ve worked in. Every tower was coupled to its transmission line through a 1:1 air-core traansformer. Two identical single-layer solenoids sharing the same axis. Between the coils was a metal picket fence. One end of the pickets was firmly grounded to the coupling cabinet. The other end of all pickets was an open circuit. Electric lines of force were intercepted by the pickets and directly shorted to ground. However, the fences had no effect on the magnetic coupling between them because the open circuit at the ends of the pickets prevented circulating currents which would have opposed magnetic coupling according to Lenz`s law.

Voila! Magnetic coupling but no electrostatic coupling between coils of a transformer.

It`s time for W8JI to turn-off his misinformation machine.

Best regards, Richard Harrison, KB5WZI

As has been noted in several posts, this is not a new approach.

The approach seeks to avoid length combinations that result in the
impedance maximums at desired operating frequencies, whether or not
those impedance maximums are ok for the ATU.

It is an approximation in several ways, including that it does not
consider the velocity factor of the transmission line, it does not
consider the effects of the environment on the impedance at the feed
point of the radiator, it assumes that higher order modes are exactly
harmonically related.

So, even then, the lengths indicated as undesirable may have
significant error incorporated.

Let's look at an example:

Consider a model of a 40m dipole of length 20.12m at 10m above average
ground, and I want to use it at 28MHz with Wireman 551 feedline of 20m
(or greater).

The wavelength at 28MHz is 10.7m, so your method would suggest that
3*10.7 or 32.1m is a "total" length to avoid, meaning that a feedline
of 32.1-20.12/2m or 22.04m is the feed length to avoid.

At this "undesirable length", the model yields a load impedance of
82+j58 which should not be particularly troublesome to most tuners at
28MHz.

In fact the corresponding modelled voltage maximum occurs with a
feedline of 19.4m (not at 22.04m), so the method is 2.64m or 12% in
error in this example. The next voltage maximum occurs at feedline
length of 24.2m, so the forecast undesirable length is roughly in the
middle of these two lengths, and about as far as you can get (ie the

most error) from the modelled voltage maxima.

>which is 160 feet on 3.6 Mhz, there are more. I hate to beat this to

>this antenna.

You don't understand it, so no one else does? I have got the picture.

Owen

Depending on the transmitter and receiver type, good ones will require
around 75 to 85 db of isolation at least.

30 feet of vertical seperation of antennas will give around 60 db of
isolation.
60 feet of vertical isolation may give around 70 db of isolation.
After that it starts to flatten out.

600 feet of horizontal seperation will give around 60 db of isolation.
It will take doubling the distance for an additional each 6 db of
isolation

That depends to some extent on the design of your receiver. Different designs have different RF-signal thresholds at which front-end desensitization will become a problem. A receiver with a broadly-tuned front end (e.g. some converted Motorola radios, most mobile ham rigs) is likely to be more prone to desense than a dedicated single-frequency receiver board having several stages of narrowly-tuned helical resonator in the RF chain.

It'll also depend on how clean your transmitter is. Broadband noise and spurs from the transmitter can cause problems for the receiver by "swamping" the desired signal with noise, independent of whatever desensitization the main transmit signal causes to the receiver front-end.

My old copy of ARRL's "FM and Repeaters" book (copyright 1972) suggests that approximately 58 dB of attenuation is required for a 600 kHz transmit/receive offset. They don't give a suggested figure for the wider 1.6 MHz offset used on the 222 band.

According to the graphs in this book, achieving 58 dB of attenuation, on the 222 band, requires approximately 20 feet of vertical separation between antennas, or approximately 100 feet of horizontal separation, assuming unity-gain antennas (e.g. halfwave dipoles). You'd need greater horizontal separation when using antennas with gain over a halfwave. You might be able to get by with less vertical separation if using gain antennas, depending on the actual pattern, feedline radiation, local reflections, and so forth.

You might want to Google around for articles which show a method for homebrewing a duplexer, using a length of surplus large-diameter hardline coaxial cable as the resonator. These have apparently been used for several years on the 6-meter band, and I recently saw a Heliax notch/pass resonator which was made for a local 2-meter repeater (it adds one additional section of receive filtering/isolation to a repeater which uses a single antenna and a commercially-built two-transmit-can, two-receive-can duplexer). The Q of such Heliax-based resonators is lower than that of conventional cans, and the insertion losses are higher.

If you don't want to install a full-fledged duplexer and use a single antenna, you might try something like a pair of 222 antennas with 20 foot or more of vertical separation, plus one band-reject (or band-pass band-reject) Heliax resonator on each one.

http://www.dallas.net/~jvpoll/dup6m/dup6m.html would be one place to start looking.

With all the J factoring ect I tend to get a bit intimidated. Then I go
back to the books from years ago. I don't have EZnec.

We had need for an antenna like that a few years ago, and bought a loop Yagi
from www.downeastmicrowave.com . No doubt similiar antennas are available in
DJ land. The one I bought had something like 80 elements on about a 3 - 4
meter boom. Price was ~U$120. Converting a TV antenna does not seem
worthwhile.

Richard,
"this can't be" because "gurus" know otherwise.
Why do you hate Tom? You don't like anything he says on his "myth overturning" web pages. He describes in a such detail and explains that "shield is an antenna" - why don't you get it? :-))))
According to Tom, RF gets induced on the outside "wire" of the shield, then it crolls to the "inside" wire of the shield around the edge of the tubing and sees another wire and jumps over, and then to coax.
If tubing or shield was the antenna, then it would receive DX and near field signals the same way. The fact that shield is shielding the near field signals should make any guru wonder.
There was ZS1 on TopBand reflector reporting that he used shielded loop and other loop antennas, and shielded loop was the only one that suppressed the local TV birdies. Tom "explained" to him "how things work" and he apologized that he did not mean to have this as an example of what I was saying.

There are other examples where shield "doesn't shield" - like link coupling made of coax with end shield open and center conductor soldered to the shield. As I mentioned I have magnetothermia machine that produces about 200W from single shielded loop, according to Tom, it should be frying the coax in the gap, with all that RF power trying to make the corner :-)

There is more nonsense on his web site.
